PREFACE

MOST engineers get together a quantity of formulae, constants and other data useful to them in the exercise of their profession, which are not always to be found in text-books. The authors, having arranged and tabulated a collection of this nature for their own use, decided to print it, believing that its pub lication would be of service to other workers in the same field.

The work thus begun has extended beyond the original plan, especially in regard to the tables of weight and measure, which have been compiled from the latest publications of the "Bureau international des Poids et Mesures" and of the Board of Trade. It appears that most published equivalents of the British Imperial and Metric measures of length are based either on a comparison made in Paris in 1818 by Arago and Kater, or on a comparison made in 1866 by Capt. A. R. Clarke of the Ordnance Survey. Similarly, Professor Miller's determination in 1844 of the avoirdupois pound as equal to 453.59265 grammes forms the usual basis of comparison for the weights of the British Imperial and Metric systems. The values adopted in this book are derived from determinations since made under the direction of the International Committee of Weights and Measures and of the Board of Trade, and legalised by Order in Council of the 19th May, 1898. In like manner the equivalents of the Russian weights and measures adopted are based on the results of Prof. D. Mendelieff's work in 1897, which were subsequently embodied in the Russian Weights and Measures Law of June, 1899.

The definitions of the electrical units given in Section II. of Part II. are taken chiefly from the Reports made to the Board of Trade in 1892 and 1894 by the Electrical Standards Committee, and the Order in Council made by her late Majesty on the

23rd August, 1894. They are defined in terms of the fundamental units of length (the centimetre), mass (the gramme), and time (the second), from which this system of units has come to be known as the C.G.S. (centimetre-gramme-second) system.

The compilation of the short section on thermal units disclosed the existence of much confusion in text-books, largely due to the various thermometric scales in use. There is also an absence of any agreement as to the terminology of the units. For instance, as Swinburne points out, there is no name for the unit of difference of temperature, "degree" being almost as primitive as "mark" or "notch."[1] Again, the British thermal unit or pound-degree (Fahrenheit) has no name; and "calorie" may mean either the gramme-degree (Centigrade) or the kilogram-degree (Centigrade). In regard to specific heat, thermal capacity, calorific power and thermal efficiency, there is a lack of authoritative definition such as has fixed for all time the electrical units.

The mining data collected in Part V. refer rather to the physical properties of ore-bodies than to the mechanical devices for their extraction. Thus, hoisting, pumping and ventilation, to which many special treatises have been devoted, are not dealt with. On the other hand, tables are given by which the calculation and valuation of ore-reserves are assisted and simplified. The latest information regarding the question of underground temperatures is summarised. The various methods in use in different countries for expressing gold ore values and for stating copper prices are compared. Finally, there is a section on mining areas which has been carefully compiled from the laws now in force in the Colonies and in foreign countries where mining is carried on.

The data relating to surveying which comprise Part VI. include a description of the conventional methods in practical use for the coordination of survey points, also a description of the use of the tacheometer, and a table for the calculation of heights and distances from tacheometric readings.

[1] *Entropy*, by James Swinburne, Westminster, 1904.

PART I. WEIGHTS AND MEASURES.

SECTION I. STANDARD UNITS.

THE METRIC SYSTEM.

Length.—The original intention of the founders of the Metric System was to select from nature itself some permanent and invariable unit of length, which could be measured with a high degree of precision, and might therefore be reproduced at will. The metre, which was the unit selected, was intended to be equal to one ten-millionth of a terrestrial meridian contained between the north pole and the equator.* The geodetic survey from Barcelona to Dunkirk, from which the length of the arc of the meridian was computed, was conducted by Méchain and Delambre between the years 1792 and 1798.

A platinum standard was then constructed and deposited in the

SINCE this book went to press the mass of a cubic decimetre of water at 4° C. has been finally agreed at 0.999972 kilogram by the delegates of the contracting States of the Metric Convention, at the General Conference, held in Paris last month. This value only differs by 2 in the sixth place of decimals from that given on page 4 (*q.v.*).

November, 1907.

purpose of constructing, restoring, and verifying new metric standards (now known as the international prototypes) to replace the standards of the Archives. Accurate copies of the new standards were also to be constructed for all the contracting States. Thirty-one standards of iridio-platinum, with a cross-section nearly of the shape of the letter X, known as the 'Tresca' form, were made, and compared with the Metre of the Archives and with one another. These were approved of by the International Committee in 1889, the standard most nearly approximating to the length of the Metre of the Archives being selected as the International Prototype Standard Metre and deposited in the Observatory at Breteuil. The remaining national prototype standards were distributed by lot to the different contracting States.

The British Prototype Standard Metre "is represented by the distance marked by two fine lines on the iridio-platinum standard bar numbered 16, when at the temperature of 0° Centigrade. This bar is deposited with the Board of Trade." *

An elaborate series of researches carried on at the International Bureau of Weights and Measures has shown that it is possible, after all, to realise the desire of the founders of the Metric System to refer the metre to a natural unit; for the standard can be expressed in terms of wave-lengths of light. In 1893 Professor A. A. Michelson found that, by the interference method, 1553163.5 wave-lengths of the red ray of cadmium, measured in air at 15° C., under an atmospheric pressure of 760 millimetres, are equal to the length of the International Prototype Standard Metre.†

Weight.—The unit of weight in the Metric System is the *Gramme*, which was originally defined "as the absolute weight of a volume of pure water equal to a cube of the one-hundredth part of a metre, and at the temperature of melting ice." As this unit, however, is rather small for accurate weighings, a weight of 1000 grammes was adopted as the practical standard. The first step in the preparation of the original standard kilogram (1000

* *Board of Trade Report*, 367 of 1898, page 9.

† See "Détermination expérimentale de la valeur du mètre en longueurs d'ondes lumineuses," A. A. Michelson, vol. xi., *Travaux et Mémoires, Bureau International des Poids et Mesures*; also, *Board of Trade Report*, 373 of 1896, page 37.

grammes) was the determination of the weight *in vacuo* of a cubic decimetre (1000 cubic centimetres) of distilled water at its maximum density. This was found to be 18,827.15 grains of the Pile de Charlemagne. A platinum standard of that weight was then constructed and deposited in the Archives of the French Republic in 1799. It is known as the *Kilogram of the Archives.* In form it is cylindrical, with height equal to the diameter and with its edges slightly rounded. When the construction of new standards for the metre and the kilogram was authorised under the Metric Convention, it was decided, since the kilogram did not represent the mass of a cubic decimetre of water with scientific accuracy, to adopt the Kilogram of the Archives as the standard unit of weight, and subsequently to determine its true relation to the mass of a cubic decimetre of distilled water at its temperature of maximum density. Accordingly, in 1879, three iridio-platinum standard kilograms were made, cylindrical in form, and of a density of 21.55. They were compared with the Kilogram of the Archives and with one another; and in 1883 the one known as K III. was adopted as the International Prototype Standard Kilogram. It has since been designated by 𝔅, although it bears no mark. Forty cylindrical iridio-platinum national prototype kilograms were then made, and compared with 𝔅 and with one another. They were approved of by the International Committee in 1889, and distributed by lot to the different contracting States. The British Prototype Standard Kilogram "is represented by the cylindrical iridio-platinum standard kilogram weight numbered 18, which is deposited with the Board of Trade." *

Capacity.—The unit of capacity in the Metric System is the *Litre*, which was intended to be the volume of a cubic decimetre, so that a litre of distilled water at 4° C. should weigh exactly a kilogram. But on further investigation it was found that this was not scientifically accurate, and it was therefore decided by the International Committee to define the Litre as "the volume occupied by the mass one kilogram of pure water at its maximum density and under normal atmospheric pressure," this definition being sanctioned at the General Conference of 1901. Recent determinations of the weight *in vacuo* of a cubic decimetre of distilled water at its temperature of maximum

* *Board of Trade Report*, 367 of 1898, page 9.

density (4° C.) made independently by Benoît, Chappuis, Macé de Lépinay and Buisson, gave very uniform results, the mean of which was found to be 0.999974 kilogram.* This value has been provisionally adopted by the *Bureau international des Poids et Mesures* pending the completion of a further elaborate series of experiments now being made at the Bureau, the results of which will be announced at the sexennial General Conference of the delegates representing the contracting States of the Metric Convention, which is to be held at Paris in October, 1907. It is anticipated that any variation between the provisional and the new values will only affect the sixth decimal place. Consequently, for all practical purposes a litre can be regarded as the volume of a cubic decimetre, the error involved being only 26 parts in a million.

The British Standard Litre "is represented by the capacity at 0° Centigrade of the cylindrical brass measure marked 'Litre, 1897' (which is deposited with the Board of Trade), and having a diameter equal to one-half its height. This Litre at 0° Centigrade when full contains one kilogram of distilled water at the temperature of 4° Centigrade, under an atmospheric pressure equal to that represented by a column of mercury 760 millimetres high at 0° Centigrade, at sea level, and at latitude 45°; the weighing being made in air, but reduced by calculation to a vacuum." †

The Metric System is in use in the following countries, to the exclusion of the older systems, except where noted:

Argentine. Almost exclusively used.
Austria. Old system still sometimes used.
Belgium.
Brazil. In common use.
Bulgaria. Old system not entirely supplanted.
Chile. In common use.
Colombia. Both old and metric systems used.
Denmark. Used by State Railways; but not in general use. It has been made compulsory by a law passed in March, 1907.
Ecuador. Old system used in commerce, metric officially.
Egypt. Old system used in commerce, metric officially and by engineers, etc.
Finland.

* See *Procès-verbaux du Comité international des Poids et Mesures*, Session 1905, p. 55.

† *Board of Trade Report*, 367 of 1898, page 9.

France.
Germany. In general use, but old measures sometimes encountered.
Great Britain. Optional, but not in general use.
Greece. Very little used.
Guatemala. Used officially but not generally.
Hungary. In general use: old system dying out.
Italy. In general use, but old system still found in the south.
Japan. Not in general use.
Luxemburg. Old system practically obsolete.
Mexico. In general use: old system dying out.
Montenegro. In general use.
Netherlands. Almost entirely used, but old system sometimes encountered.
Norway.
Peru. Only used by Government.
Philippine Islands.
Porto Rico.
Portugal.
Russia. Optional, but not in general use.
Servia. In general use.
Siam. Used by railways and public works.
Spain. In general use, but old measures still encountered.
Sweden.
Switzerland.
United States of America. Optional, but not in general use.
Uruguay.
Venezuela. Only used officially.

THE BRITISH IMPERIAL SYSTEM.

Length.—The British Imperial Standard unit of length is the *Yard*. The 'line' standard constructed by Bird in 1760 having been lost in the fire which destroyed the Houses of Parliament in 1834, the present standard yard was made by Messrs. Baily and Sheepshanks in 1843, by reference to the 5-foot brass Shuckburgh scale of 1796, the two iron standards made for the Ordnance Survey in 1826-7, the brass tubular scale of the Royal Astronomical Society, and the Kater scale of 1831 made for the Royal Society.

It is a solid bar of 'Baily's metal' (16 parts by weight of

copper, 2½ of tin, and 1 of zinc) 38 inches long, with a cross-section 1 inch square. Near its ends are two circular wells half an inch deep. At the bottom of these wells, and consequently on the 'neutral plane' of the bar, are gold studs, on which the fiducial lines are engraved, the distance between them forming the British Imperial Standard Yard at a temperature of 62° Fahr. It was legalised by the Standards Act of 1855. It is preserved at the Standards Office, Westminster, and has been in the custody of the Board of Trade since 1866.

Thirty-nine copies of this standard were made of the same material and dimensions. Four of these are specially designated Parliamentary Copies, which, by the Weights and Measures Act of 1878, must be compared with each other once in every ten years and with the Imperial Standard once in every twenty years, in order to ensure the perpetuation of the standard. These Parliamentary Copies are stamped with the temperature at which they represent the true standard, namely:

P.C. 2 in the custody of the Royal Mint: standard at 61.94° F.
P.C. 3 „ „ Royal Society: standard at 62.10° F.
P.C. 4 „ „ Royal Observatory, Greenwich: standard at 62.16° F.
P.C. 5 „ „ New Palace, Westminster: standard at 61.98° F.

The remaining thirty-five copies were distributed to various nations and scientific institutions.

Weight.—The British Imperial standard unit of weight is the *Avoirdupois Pound* of 7000 grains. The standard troy pound of 5760 grains having been destroyed in the fire of 1834, the avoirdupois pound of 7000 grains was substituted as the standard, on the recommendation contained in a report submitted by the Parliamentary Standards Committee, Dec. 21, 1841; and the present standard pound was constructed by Prof. W. H. Miller in 1844 by reference to a troy pound belonging to the Royal Society, and a troy pound the property of Prof. Schumacher. It is of platinum, cylindrical in form, 1.35 inches high and 1.15 inches in diameter, with a density of 21.1572. It has a small groove in its circumference to permit of its being lifted with an ivory fork, and is marked 'P.S. 1844. 1 lb.'* on its upper surface. It was legalised in 1855, and is preserved at the Standards

* P.S. signifies Parliamentary Standard.

Office, Westminster, in the custody of the Board of Trade. As in the case of the unit of length, there are four Parliamentary Copies. Compared with the standard,

No. 1 P.C., which is in the custody of the Royal Mint, is 0.00051 grain too heavy.
No. 2 P.C., in the custody of the Royal Society, is 0.00089 grain too light.
No. 3 P.C., in the custody of the Royal Observatory, Greenwich, is 0.00178 grain too light.
No. 4 P.C., in the custody of the New Palace, Westminster, is 0.00314 grain too light.

The Weights and Measures Act of 1878 provides that one additional Parliamentary copy of the Standard Yard and of the Pound should be made. These were constructed and approved of by the Board of Trade, and were accordingly legalised by an Order in Council of Aug. 3, 1886.* The Board of Trade secondary standards, by which all other standards are tested, are required by the Act to be re-verified once every five years by comparison with these new Parliamentary copies.

Capacity.—The British Imperial standard unit of capacity is the *Gallon*, which is the volume of ten Imperial standard pounds of distilled water weighed in air against brass weights, with the water and air at a temperature of 62° Fahr. and under a barometric pressure of 30 inches. The standard is of brass, with a diameter equal to its depth, and bears the date of 1828. It is in the custody of the Board of Trade, and is deposited at the Standards Office, Westminster. A standard Bushel (equal to 8 gallons) is also preserved at the Standards Office as the unit of dry measure It is of gun-metal, with a diameter equal to twice its depth. It dates from 1824, and was verified in 1825.

The Weights and Measures Act of 1824 gives the weight of a cubic inch of distilled water under standard conditions as 252.458 grains, a value derived from weighings made by Sir George Shuckburgh in 1798† and Captain Henry Kater in 1821.‡ On this basis, 277.274 and 2218.192 cubic inches are the volumes of the Imperial gallon and bushel respectively.

* *Board of Trade Report* 9, Sess. 2 of 1886, p. 1. This Parliamentary Copy of the pound is referred to as No. 5 P.C., and is deposited at the Standards Office.

† *Philosophical Transactions, Royal Society*, 1798, p. 133.

‡ *Phil. Trans., Roy. Soc.*, 1821, pp. 316, 326.

In 1889, Mr. H. J. Chaney determined the mass of a cubic inch of distilled water, freed from air, weighed in air against brass weights of a density of 8.143, with the water and air at a temperature of 62° Fahr. and the barometer at 30 inches, to be 252.286 grains ± .0002 grain.* The weight of a cubic foot of such water under similar conditions would therefore be 62.278601 lbs., and the volume of the Imperial gallon and of the bushel 277.46288 and 2219.70304 cubic inches respectively. Although no direct determination of the weight of a cubic inch of water has since been made, the foregoing values have been superseded. It has been found that 1 litre = 1.000026 cubic decimetres (see p. 4), and that 4.5459631 litres = 1 Imperial gallon (see p. 15); therefore, under standard conditions:

The weight of 1 cubic inch of water at 62° F. = 252.3253 grains.
" 1 cubic foot of water at 62° F. = 62.2883 lbs.
and the volume of 1 Imperial gallon = 277.420 cubic inches.

These values have been provisionally adopted by the Board of Trade Standards Department.

The Imperial Weights and Measures are now legally in force in the following Colonies, etc.:

Antigua.	Jamaica.	Sierra Leone.
Barbadoes.	Malta.	Straits Settlements.
Bermuda.	Natal.	South Australia.
British Guiana.	Nevis.	St. Christopher.
British Honduras.	New Brunswick.	St. Helena.
Canada.	New South Wales.	St. Vincent.
Cape of Good Hope.	New Zealand.	Transvaal.
Cyprus.	Nova Scotia.	Tobago.
Dominica.	Orange River Colony.	Trinidad.
Grenada.	Queensland.	Vancouver's Island.
Hong Kong	Rhodesia.	Victoria.
	Western Australia.†	

An Act of 1897 permits the use of Metric Weights and Measures in the United Kingdom, and provides that the Board of Trade standards shall include metric standards.

* *Trans. Royal Society*, 1892, pp. 331-354; also *Board of Trade Report*, 302 of 1889, p. 10.

† See *Board of Trade Report* 9, Sess. 2, 1886. The Orange River Colony, the Transvaal, and Rhodesia have since been included.

THE UNITED STATES OF AMERICA.

The weights and measures of the United States are practically identical with those of the British Imperial System, with the exception of the measures of capacity which, although defined in units having the same names and sub-divisions, have quite different volumes.

The use of the Metric System is recognised by an Act of 1866. Prototype standard meters, Nos. 21 and 27, and kilograms, Nos. 4 and 20, were received from the International Bureau of Weights and Measures in 1889, and *Meter No.* 27 and *Kilogram No.* 20 were adopted as the National Prototype Standards in 1890. In Bulletin No. 26 of the 5th April, 1893, issued by the U.S. Coast and Geodetic Survey with the approval of the Secretary of the Treasury, the United States Government recognises "the International Prototype Meter and Kilogram* as fundamental standards," and states that "the customary units, the yard and the pound, will be derived therefrom in accordance with the Act of July 28, 1866." The metric equivalents of the yard and the pound legalised by this Act differ in a slight degree from the British equivalents legalised in 1898, but the differences are so small that, for all practical purposes, they may be disregarded (see pp. 36 and 40). In 1901 the custody of the national standards was transferred from the Coast and Geodetic Survey to the Bureau of Standards, which was established in that year under the Department of Commerce and Labor.

Liquid Measure.—The standard unit of liquid measure is the *U.S. Gallon*, which is derived from the Queen Anne wine gallon of 1707. It is defined as having a volume of 231 cubic inches. It is also the standard unit of Apothecaries' Fluid Measure.

Dry Measure.—The standard unit of dry measure is the *U.S. Bushel*, which is derived from the old Winchester "struck" bushel. It is defined as having a volume of 2150.42 cubic inches. The U.S. Bushel measure has the form of an inverted frustum of a right cone of the following dimensions

* *i.e.* the international metric standards deposited at Breteuil Observatory, near Paris.

(inside measurement): top diameter, $19\frac{1}{2}$ inches; bottom diameter, $18\frac{1}{2}$ inches; depth, 8 inches.

The *dry* measures are considerably larger than the *liquid* measures of the same name; for instance, the *dry* U.S. gallon ($\frac{1}{8}^{\text{th}}$ bushel) = 268.8025 cubic inches, while the *liquid* U.S. gallon = 231 cubic inches.

RUSSIA.

Length.—In 1833 the Russian units of length were defined in terms of British feet, and a standard *Sagene* (equal to 7 British feet) was constructed and compared with the British Imperial Standard Yard, and subsequently legalised by an Act of Oct. 1835. A standard *Archine*, equal to $\frac{1}{3}$ sagene, constructed by Prof. Kupffer, is recognised as the standard unit of length by a law passed in June 1899. It is an iridio-platinum 'line' standard of Tresca form, standard at $16\frac{2}{3}$° C. (62° F.), and is inscribed $\frac{\text{H}}{\text{II}}$ 1894. It is defined as equal to 28 British inches or 0.711200 ± 0.000001 metre.

Weight.—The standard unit of weight is the *Funt* or Russian pound. The standard Funt is of iridio-platinum of a density of 21.51 at $16\frac{2}{3}$° C., and is inscribed $\frac{\text{H}}{\text{II}}$ 1894. It was reproduced from the platinum funt of 1835, which was derived from a funt of 1747. It is defined as equal to 0.40951241 ± 0.00000001 kilogram.

Capacity.—The standard units of liquid and dry measures are respectively the *Vedro* and the *Tchetverik*. The Vedro is defined as the volume of 30 funts, weighed *in vacuo*, of distilled water at a temperature of $16\frac{2}{3}$° C. The Tchetverik is defined as the volume of 64 funts of such water under similar conditions.

The national standards are deposited at St. Petersburg.

The law of June 1899, which became effective on Jan. 1, 1900, permits the use of the Metric System.

CHINA.

The Weights and Measures of China have different local names and values.* The only standards legally in use for international

* See Dr. Williams' *Chinese Commercial Guide.*

purposes are those adopted in the foreign treaties for the payment of duties at the Foreign Maritime Customs. By Rule IV. of the Rules of Trade signed at Shanghai on Nov. 8, 1858, the weight of a *Pikul* (Tam) of 100 Katis (Kan or Chin) is defined as equal to 133⅓ lbs. avoirdupois, and the length of a *Chang* of 10 Ch'ih as equal to 141 British inches. Similar equations were adopted in the Rules of Trade appended to other foreign treaties. The standard Chinese weights verified for Hong Kong by the Board of Trade in 1900-01 were a *Tam* of 133⅓ lbs., a *Kan* of 1⅓ lbs., and a *Tael* of 1⅓ oz. avoirdupois. The Standard *Ying-tsao Ch'ih* or foot of the Chinese Board of Works, from which all measures connected with the Revenue, whether of length, capacity, or weight, are derived, is approximately equal to 12.5 British inches;* but different local commercial standards obtain throughout the whole of China. A standard Chinese '*Chek*' (Ch'ih) of 14⅝ inches, divided into 10 'Tsun,' and each Tsun into 10 'Fan,' was verified by the Board of Trade Standards Department in 1896-97 for Hong Kong, where both British and Chinese weights and measures are used.† Measures of capacity are seldom used—grains, liquids, etc., being mostly bought and sold by weight.

JAPAN.

In March 1891, a law was passed, with effect from Jan. 1, 1893, permitting the use of the Metric System. The same Act re-organised the national weights and measures, and defined them in terms of the metric units, prototype standards of which had been received in 1889.

Length.—The standard unit of length is the *Shaku*, which is defined as $\frac{10}{33}$ of the length of the national iridio-platinum prototype metre, standard at 0°.15 Centigrade. The unit of square or land measure is the *Bu* or *Tsubo*, which is equal to a square, each side of which measures 6 shakus.

Weight.—The standard unit of weight is the *Kwan*, which is defined as equal to $\frac{15}{4}$ of the weight of the national iridio-platinum prototype kilogram. The density of a Japanese standard iridio-platinum Kwan weight of 3750 grammes was determined

* *Board of Trade Report* 9, Sess. 2, 1886, pp. 46 and 49.

† *Board of Trade Report*, 392 of 1897, p. 6.

as 21.5423 at 0° C. by the Board of Trade Standards Department in 1896-97.*

Capacity.—The standard unit of capacity is the *Shô*, which is defined as equal to 1.80391 litres.

The national standards are in the custody of the Minister of Agriculture and Commerce at Tokio.

BRITISH INDIA.

Various weights and measures are in use in India, the local standards being kept by the district and municipal authorities.

Length.—The British Imperial yard, foot, and inch are statutory by the Measures of Length Act of 1889. This Act does not refer to square measures. A brass standard yard was verified by the Board of Trade Standards Department for the Government of India in 1889. It is inscribed: "Accurate copy of Imperial Standard Yard, 1889, Calcutta. Standard Yard at 85 degrees Fahrenheit." At the same time two similar standards were also supplied to the Presidencies of Bombay and Madras.†

Weight.—The standard unit of weight is the *Tola*, which is equal to 180 grains, the weight of the rupee. Primary standard iridio-platinum weights of 30, 20, and 10 Tolas were verified by the Board of Trade Standards Department for the Calcutta and Bombay Mints in 1892.‡

Capacity.—Measures of capacity are seldom used by the natives —grain, liquids, etc., being usually bought and sold by weight. Measures are made to contain certain weights of some commodities. They are really 'measures of weight,' and are named by the weights which they represent.

THE STRAITS SETTLEMENTS.

The Straits Settlements Ordinance No. VII. of 1886 assimilates the weights and measures of the colony to the British Imperial System, with the exception of certain customary native weights, such as the Tahil, Kati, and Pikul, to which are assigned values in terms of British Imperial weights (see p. 30). The Board

* *Board of Trade Report*, 392 of 1897, p. 6.

† *Board of Trade Report*, 302 of 1889, p. 6.

‡ *Board of Trade Report*, 364 of 1893, p. 13.

of Trade Standards Department assisted in the drawing up of the Ordinance, and verified a large number of copies of the Imperial standards for the colony.* They have also supplied other standards, such as the Kati = $1\frac{1}{3}$ lbs. avoirdupois, and a quarter-Chupah (2 Imperial gills), which contains ten fluid ounces of distilled water at 62° Fahr.† The standards of the colony are deposited at Singapore.

SOUTH AFRICA.

In Natal, the British Imperial is the legal system of weights and measures.‡ This is also the case in Cape Colony, British Bechuanaland, the Orange River Colony, the Transvaal, and Rhodesia, except that there is a special system of land measure. The unit of land measure is a foot "of such length that 1000 of such feet shall be equal to 1033 English feet as now by law defined and established for lineal measurement in England."§ This unit is termed the *Cape Foot*, and is a survival of the Rhynland foot used during the Dutch occupation of the Cape of Good Hope. Twelve Cape feet make a *Rood* and 600 square roods a *Morgen*. This system is used in all land surveys, and standard Roods are deposited with the Surveyor-General of each Colony.

EGYPT.

The use of the metric system is permitted by a decree issued by the Khedive Ismail in 1873. It has been adopted by the government for all purposes except the measurement of areas of land and the tonnage of ships, and is used by the public works, post office, customs and railway departments. A decree issued by the Khedive Mohamed Tewfik on the 28th April 1891, with effect from the 1st of January 1892, recognises the International Prototype Metre and Kilogram‖ as fundamental

§ *Cape Colony Law*, No. 9 of 1859.

‖ *i.e.* the international metric standards deposited at Breteuil Observatory, near Paris.

standards from which the Egyptian units of length, weight, and capacity are derived by means of equivalents stated in the decree (see page 17).

The old weights and measures are still in general use, the units being as follows:

Length.—There are several different units of length, namely: the *Diraâ baladi* or 'town' diraâ; the *Diraâ mimari*, which is used in building, etc.; the *Pike Istambuli* or Constantinople Pike, used in measuring cloth; and the *Kassabah*, used in land surveying. The *Feddan* of $333\frac{1}{3}$ square kassabahs is the legal unit of land area.

Weight.—The standard unit of weight is the *Dirhem* (drachm).

Capacity.—The standard unit of capacity is the *Ardeb*.

SECTION II. COMPARISON OF STANDARD UNITS.

THE METRIC AND BRITISH IMPERIAL SYSTEMS COMPARED.

In 1894-95 a comparison of the Yard with the Metre was made under the directions of the Board of Trade and the International Committee of Weights and Measures. The Parliamentary Copy of the Standard Yard, P.C. VI.. was first carefully compared with the Imperial Standard Yard at the Standards Office, Westminster. It was then taken to the International Bureau of Weights and Measures at Breteuil and compared with the International Prototype Standard Metre,* and the following result was confirmed at a meeting of the Metric Conference in September 1895.† At 16°.667 Centigrade the Imperial Yard is equal to 0.9143992 Metre, the temperature 16°.667 C. being taken as equal to 62° Fahrenheit; or, conversely, at 16°.667 C. (62° F.) the Metre is equal to 39.370113 inches.‡

In 1883 a comparison of the Pound and the Kilogram was made in the same manner. A copy of the pound was compared

* *Board of Trade Report*, 432 of 1895, pp. 3 and 23.

† *Board of Trade Report*, 373 of 1896, p. 37.

‡ *Détermination du Rapport du Yard au Mètre*, by Dr. Benoît (Director of the International Bureau of Weights and Measures), Paris, 1896.

with the Imperial Standard at the Standards Office, and then with the International Prototype Kilogram at the International Bureau, with the following result: the Imperial Avoirdupois Pound weighed *in vacuo* at 0° Centigrade is equal to 453.5924277 Grammes; or, conversely, the Kilogram is equal to 15432.35639 Grains.*

In comparing the units of capacity of the two systems, the weight *in vacuo* of distilled water at 4° C. contained in a Litre is compared with the weight *in air* of distilled water at 16°.667 C. (62° F.) contained in a Gallon. The Imperial Gallon is equal to 4.5459631 Litres; or, conversely, the Litre is equal to 1.75980 Pints. The Board of Trade equivalents of Metric and Imperial Weights and Measures, legalised by an Order in Council of May 19, 1898, are based on the foregoing comparisons, which may be summarised as follows:

1 Yard = 0.9143992 Metre.
1 Metre = 39.370113 Inches.
1 Pound = 453.5924277 Grammes.
1 Kilogram = 15432.35639 Grains.
1 Gallon = 4.5459631 Litres.
1 Litre = 1.75980 Pints.

The French Toise and the Austrian Klafter were the units of length formerly used in most of the European geodetic surveys. They are, however, no longer in use, having been superseded by the Metre. Compared with the Imperial Yard,

1 Toise = 2.13151116 Yards.
1 Klafter = 2.07403483 Yards.
1 Metre = 1.09361426 Yards.†

THE UNITED STATES, THE METRIC, AND THE BRITISH IMPERIAL SYSTEMS.

Since 1893 the International Prototype Meter and Kilogram (deposited at Breteuil Observatory, near Paris) have been regarded in the United States as fundamental standards, from

* *Travaux et Mémoires, Comité international des Poids et Mesures*, Tome IV., 1885; also *Board of Trade Annual Weights and Measures Report*, 1884.

† H. J. Chaney, *Our Weights and Measures*, London, 1897, p. 67.

which all units of weight and measure are derived in terms of the equivalents legalised by the Act of July 1866.* The U.S. yard is reproduced from the meter in terms of the equation: 1 yard $= \frac{3600}{3937}$ meter, while the British equivalent is: 1 yard = 0.9143992 metre. Therefore

1 U.S. Yard = 1.000002875 Imp. Yards,

a difference of only 2.875 in a million. U.S. and British measures of length can therefore be regarded as practically identical.

The British equivalent:

1 Avoirdupois Pound = 453.5924277 Grammes

has been adopted by the U.S. Bureau of Standards. U.S. and British weights are therefore exactly alike.

The Bureau of Standards equivalents of the U.S. units of capacity are:

1 U.S. Liquid Gallon of 231 cubic inches = 3.785434497 Liters.†
1 U.S. Bushel of 2150.42 cubic inches = 0.352392816o Hectoliter.

The British equivalents are: 1 Imp. Gallon = 4.5459631 Litres, and 1 Imp. Bushel = 0.363677048 Hectolitre. Therefore

1 U.S. Liquid Gallon = 0.83270 Imp. Gallon.
1 Imp. Gallon = 1.20091 U.S. Gallons.
1 U.S. Bushel = 0.96897 Imp. Bushel.
1 Imp. Bushel = 1.03202 U.S. Bushels.

COMPARISON OF THE RUSSIAN WITH THE METRIC AND THE BRITISH IMPERIAL SYSTEMS.

In 1897 Prof. D. Mendelieff, acting on the authority of the Russian Government, determined the values of the Russian standard units in terms of those of the Metric System by a series of experiments made at the International Bureau of Weights and Measures, which values were subsequently legalised by the Act of June 1899 (see page 10). The units of capacity are derived from the unit of weight by reference to the volume of distilled water at $16\frac{2}{3}°$ C. The equivalents on which the conversion

* Bulletin No. 26, *U.S. Coast and Geodetic Survey*, 5th April, 1893.

† In the United States a liter is regarded as the volume of a cubic decimeter, which, according to the most recent determination (see p. 4), involves an error of only 26 parts in a million.

tables given on page 42 are based, may be summarised as follows:

1 Archine = 28 British Inches or 0.711200 Metre.*
1 Funt = 409.51241 Grammes.
1 Vedro = 12.2993285 Litres.
1 Tchetverik = 26.2385674 „

COMPARISON OF THE EGYPTIAN WITH THE METRIC AND THE BRITISH IMPERIAL SYSTEMS.

A decree issued by the Khedive Mohamed Tewfik on the 28th April, 1891, with effect from the 1st of January, 1892, defines the Egyptian units of length, weight, and capacity in terms of the international metric standards (deposited at Breteuil Observatory, near Paris) as follows:

1 Diraâ baladi = 0.580 Metre.
1 Diraâ mimari = 0.750 Metre.
1 Kassabah = 3.550 Metres.
1 Dirhem = 3.12 Grammes.
1 Ardeb = 1.98 Hectolitres.

The decree also embodies a table of the legal Metric and British Imperial equivalents of the Egyptian weights and measures (see page 52).

In 1902 and 1903 the Board of Trade Standards Department verified standard Rotl and Oke weights for the Sudan Customs, 1 rotl being taken as equal to 0.990492 lb. and 1 oke as equal to 2.751367 lbs., these being the Egyptian legal equivalents.†

*28 British inches = 0.7111995 metre.

†*Board of Trade Reports*, 334 of 1903, p. 7, and 348 of 1904, p. 6.

Kilolitre, - -	kl.	1000 l.	1 $m.^3$

NOTE.—The weight *in vacuo* of a cubic decimetre of distilled water at 4° C. is .999974 kilogram (see page 4). Therefore for all practical purposes a litre may be regarded as the volume of a cubic decimetre, the error involved being only 26 parts in a million.

The above metric symbols are those adopted by the *Comité international des Poids et Mesures.*†

† *Procès-verbaux*, Session 1905, p. 175.

THE BRITISH IMPERIAL SYSTEM.

Avoirdupois or Commercial Weight.

27.34375 grains = 1 drachm.
16 drachms = 1 ounce (oz.) = 437.5 grains.
16 ounces = 1 **pound** (lb.) = 256 drachms = 7000 grains.
28 pounds = 1 quarter (qr.) = 448 ounces.
4 quarters = 1 hundredweight (cwt.) = 112 pounds.
20 hundredweights = 1 ton = 80 quarters = 2240 pounds.

1 stone = 14 pounds : 1 cental = 100 pounds :
20 centals = 1 'short' ton of 2000 pounds.

The ton of 2240 lbs. is usually termed the 'long' ton, in contradistinction to the 'short' ton of 2000 lbs. To convert long into short tons, multiply by 1.12 ; or from short into long, divide by 1.12.

Ounces (avoir.) in Decimals of a Pound (avoir.).

Ounces.	Pound.	Ounces.	Pound.	Ounces.	Pound.
¼	.0156	5	.3125	10½	.6562
½	.0312	5½	.3437	11	.6875
¾	.0468	6	.375	11½	.7187
1	.0625	6½	.4062	12	.75
1½	.0937	7	.4375	12½	.7812
2	.1250	7½	.4687	13	.8125
2½	.1562	8	.5	13½	.8437
3	.1875	8½	.5312	14	.875
3½	.2187	9	.5625	14½	.9062
4	.25	9½	.5937	15	.9375
4½	.2812	10	.625	15½	.9687

Troy Weight.

(Used for the weighing of precious metals.)

24 grains = 1 pennyweight (dwt.).
20 pennyweights = 1 **ounce** (oz. troy) = 480 grains.
12 ounces = 1 pound (lb. troy) = 240 pennyweights = 5760 grains.

The grain is the same in both troy and avoirdupois weights.

The troy pound is seldom used.

The Diamond Carat and the Pearl Grain, although in general use, are not legal weights. They are thus defined by the Board of Trade: 151½ diamond carats or 600 pearl grains = 1 troy ounce ; therefore a diamond carat = 3.168$\dot{3}$ grains (205.30 milligrams) and a pearl grain = 0.8 grain (51.84 milligrams).*

* *Board of Trade Reports*, 330 of 1888, p. 13, and 302 of 1889, p.2.

Comparison of Avoirdupois and Troy weights.

1 lb. avoir. = 14.583 oz. troy, logarithm = 1.1638568.
1 oz. „ = 0.9114583 oz. „ „ = 9.9597368.
1 oz. troy = 1.097143 oz. avoir., „ = 0.0402632.

Grains and Dwts. in Decimals of a Troy Oz.

11 „	= .4583 „	23 „	= .9583 „
12 „	= .5 „	24 „	= 1.0 „

Apothecaries' Weight.

20 grains = 1 scruple (℈.)
3 scruples = 1 drachm (ʒ.) = 60 grains.
8 drachms = 1 ounce (℥.) = 480 grains.
12 ounces = 1 pound (lb.) = 5760 grains.

Drugs are now often weighed by avoirdupois weight. The scruple and drachm are not introduced into the British Pharmacopœia, but are still used in prescriptions.

The ounce and pound are the same as in troy weight, while the grain is the same in avoirdupois, troy and apothecaries' weights.

Lineal Measure.

12 inches = 1 foot.
3 feet = 1 **yard** = 36 inches.
5½ yards = 1 rod, pole or perch = 16½ feet = 198 inches.
40 rods = 1 furlong = 220 yards = 660 feet.
8 furlongs = 1 statute mile = 1760 yards = 5280 feet.

1 link = 7.92 inches = 0.66 foot; 100 links = 1 Gunter's chain = 66 feet; 80 chains = 1 statute mile; 6 feet = 1 fathom; 3 statute miles = 1 league; 6075.6 feet = 1 geographical mile.

Inches expressed in Decimals of a Foot.

THE UNITED STATES OF AMERICA.

Avoirdupois or Commercial Weight.

27.34375 grains = 1 dram.
16 drams = 1 ounce (oz.) = 437.5 grains.
16 ounces = 1 pound (lb.) = 7000 grains.
14 pounds = 1 stone.
2 stones = 1 quarter (qr.) = 28 pounds.
4 quarters = 1 hundredweight (cwt.) = 112 pounds.
20 hundredweights = 1 'long' ton = 80 quarters = 2240 pounds.
Also: 100 pounds = 1 quintal; 20 quintals = 1 'short' ton of 2000 pounds.

Troy Weight.

24 grains = 1 pennyweight (dwt.).
20 pennyweights = 1 ounce (oz. troy) = 480 grains.
12 ounces = 1 pound (lb. troy) = 240 dwts. = 5760 grains.

Apothecaries' Weight.

20 grains = 1 scruple (℈).
3 scruples = 1 dram (℥) = 60 grains.
8 drams = 1 ounce (℥) = 24 scruples = 480 grains.
12 ounces = 1 pound = 288 scruples = 5760 grains.

In avoirdupois, troy, and apothecaries' weights the grain is of the same weight, and in troy and apothecaries' weights the ounce and pound are the same.

Lineal Measure.

12 inches = 1 foot (ft.).
3 feet = 1 yard (yd.) = 36 inches.
5½ yards = 1 rod, pole or perch = 16½ feet.
40 rods = 1 furlong = 220 yards = 660 feet.
8 furlongs = 1 statute mile = 1760 yards = 5280 feet.
3 miles = 1 league.

Also: 7.92 inches = 1 link; 100 links = 1 Gunter's chain = 66 feet; 80 chains = 1 mile.

3 inches = 1 palm; 4 inches = 1 hand; 9 inches = 1 span.
6 feet = 1 fathom; 1 cable's length = 120 fathoms.

Square Measure.

144 square inches = 1 square foot.
9 square feet = 1 square yard = 1296 square inches.
30¼ square yards = 1 square rod = 272¼ square feet.
40 square rods = 1 rood = 1210 square yards.
4 roods = 1 acre = 43560 square feet = 10 square chains.
640 acres = 1 square mile or section.
36 square miles = 1 township.

Cubic Measure.

1728 cubic inches = 1 cubic foot.
27 cubic feet = 1 cubic yard.
16 cubic feet = 1 cord.
24¾ cubic feet = 1 perch of stone or masonry.
128 cubic feet = 1 cord of wood.

Liquid Measure.

4 gills	= 1 pint (pt.)	= 28.875	cubic inches.
2 pints	= 1 quart (qt.)	= 57.75	„
4 quarts	= 1 **gallon** (gal.)	= 231.0	„
31½ gallons	= 1 barrel.		
2 barrels	= 1 hogshead	= 63 gallons.	
2 hogsheads	= 1 pipe or butt	= 126 gallons.	
2 pipes	= 1 tun	= 252 gallons.	

Also: 42 gallons = 1 tierce; 2 tierces = 1 puncheon = 84 gallons.

Apothecaries' Fluid Measure.

60 minims (m)	= 1 fluid drachm (f.ʒ) =	0.2256	cubic inch.
8 fluid drachms	= 1 fluid ounce (f.ʒ) =	1.8047	„ inches.
16 fluid ounces	= 1 pint (O.) =	28.875	„ „
8 pints	= 1 **gallon** =	231.0	„ „

Dry Measure.

2 pints	= 1 quart	= 67.2006	cubic inches.
4 quarts	= 1 gallon	= 268.8025	„
2 gallons	= 1 peck	= 537.605	„
4 pecks	= 1 **bushel**	= 2150.42	„
8 bushels	= 1 quarter.		
21½ bushels	= 1 barrel (dry).		
36 bushels	= 1 chaldron.		

Note that the dry measures are larger than the liquid measures of the same names.

RUSSIA.

Commercial Weight.

96 dolis	= 1 zolotnik.
96 zolotniks	= 1 **funt.**
40 funts	= 1 pood.

Other weights sometimes used are: the loth = 3 zolotniks; the lana = 8 zolotniks; the berkovetz = 10 poods; and the packen = 3 berkovetz.

Gold ore values are expressed in zolotniks per 100 poods (see pages 103 and 104).

Apothecaries' Weight.

60 medical grains	= 1	medical	drachme.	
8 „ drachmes	= 1	„	once.	
12 „ onces	= 1	„	**funt**	= 84 zolotniks.

Drugs are now mostly weighed by metric weights.

Lineal Measure.

10 totchkas	= 1	liniia.
17.5 liniias	= 1	vershok.
16 vershoks	= 1	**archine.**
3 archines	= 1	sagene = 48 vershoks.
500 sagenes	= 1	verst.

The British Imperial foot and inch and the metre are also in use.

The archine is used in mining and trade, the sagene in land measurement, and the foot and inch in engineering works.

Square Measure.

256 square vershoks = 1 square archine.
9 square archines = 1 square sagene = 2304 square vershoks.
2400 square sagenes = 1 **dessiatina.**
104.16 dessiatinas = 1 square verst = 250,000 square sagenes.

Cubic Measure.

4096 cubic vershoks = 1 cubic archine.
27 cubic archines = 1 **cubic sagene** = 110,592 cubic vershoks.

Liquid Measure.

10 tcharkas = 1 schtoff.
10 schtoffs = 1 **vedro.**
16 boutylkas (bottles of wine) = 1 vedro.
20 boutylkas (bottles) = 1 vedro.

Dry Measure.

8 garnetz = 1 **tchetverik.**
4 tchetveriks = 1 osmina.
2 osminas = 1 tchetvert.
12 tchetverts = 1 last.

---

1 cubic sagene = { 789.67123 vedros.
46.2698 tchetverts.

CHINA.

Commercial Weight.

16 liang (taels or tahils) = 1 chin (kan or kati) = $1\frac{1}{3}$ lbs. avoir.
100 chin = tan (tam or pikul) = $133\frac{1}{3}$ „

Silver Weight.

10 ssŭ = 1 hao (thousandths).
10 hao = 1 li (hundredths—'cash').
10 li = 1 fên (tenths—'candareen').
10 fên = 1 ch'ien ('mace').
10 ch'ien = 1 liang (tael or tahil) = $1\frac{1}{3}$ oz. avoir.

Lineal Measure.

10 fan = 1 ts'un = 1.41 British inches.
10 ts'un = 1 ch'ih (covid) = 14.1 „
10 ch'ih = 1 chang (rod) = 141 „

The foregoing values are those of the British Treaty of 1858. They are used in the payment of duties at the Foreign Maritime Customs. At Hong Kong, where both British Imperial and Chinese weights and measures are in use, the present standard *chek* or *ch'ih* was verified by the Board of Trade. It measures $14\frac{5}{8}$ inches, and is therefore 0.525 inch longer than the *ch'ih* of the British Treaty. The standard *ying-tsao ch'ih* of the Chinese Board of Works is approximately 12.5 inches. The Hong Kong weights are identical with those of the British Treaty.

Itinerary Measure.

5 ch'ih (covids) = 1 pu (pace).
360 pu = 1 li (about $\frac{1}{3}$ mile).
250 li = 1 tu (degree).

Land Measure.

5 ch'ih (covids) = 1 kung (bow).
240 square kung = 1 mou (rood).

Cubic Measure.

100 cubic ch'ih = 1 fang or ma.

Measures of Capacity.

10 ho = 1 shêng = approx. 2 Imp. pints.
10 shêng = 1 tou.
5 tou = 1 hu.

JAPAN.

Weight.

10 shi = 1 mô.
10 mô = 1 rin.
10 rin = 1 fun.
10 fun = 1 mommē.
160 mommē = 1 kin.
1000 mommē = 1 **kwan.**

Lineal Measure.

10 shi = 1 mô.
10 mô = 1 rin.
10 rin = 1 bu.
10 bu = 1 sun.
10 sun = 1 **shaku.**
6 shaku = 1 ken.
60 ken = 1 chô = 360 shaku.
36 chô = 1 ri = 12960 shaku.

For cloth measurement the kujira shaku is used. It is equal to 1 shaku 2 sun 5 bu.

Square Measure.

10 shaku = 1 gô.
10 gô = 1 **bu or tsubo.**
30 tsubo = 1 sē.
10 sē = 1 tan = 300 tsubo.
10 tan = 1 chô = 3000 tsubo.

A bu or tsubo equals 36 square shaku (1 square ken) *of lineal measure.*

Measures of Capacity.

10 shaku = 1 gô.
10 gô = 1 **shô.**
10 shô = 1 to.
10 to = 1 koku = 100 shô.

In the above tables the same name is sometimes applied to units having no connection with each other. For instance, the *shaku* as a lineal measure is quite different from the *shaku* of square measure, which again has no connection with the *shaku* of capacity.

BRITISH INDIA.

The following weights are based on the *tola*, which is the weight of a rupee (180 grains). They are officially recognised, and are used on the railways, etc., but numerous local weights of varying value obtain throughout India. The Burmese *viss* of 100 *tikals* = 3.65 lbs. avoir. exactly.*

* See *Board of Trade Report*, 326 of 1901, p. 5.

Weight.

180 grains = 1 **tola.**
80 tolas = 1 seer.
40 seers = 1 maund.
20 maunds = 1 kandy.

Lineal Measure.

The Imperial yard, foot and inch are statutory by Act 2 of India, 1889. Various native measures, which are mostly based on the *gaz* or yard, are also used.

Square Measure.

The *biga* is the common unit of land measure. It varies in size in almost every village.

The Bengal biga = approximately 1600 sq. yards.
The N.W. Province „ = „ 3025 „
The Bombay „ = „ 3927 „

In Madras, the unit is the *kani* = approximately 6400 sq. yards.

THE STRAITS SETTLEMENTS.

Ordinance No. VII. of 1886 assimilates the weights and measures used in the Straits Settlements to the British Imperial weights and measures, with the exception of the following weights:

10 hoons = 1 chee.
10 chee = 1 **tahil** (tael) = $1\frac{1}{3}$ oz. avoir.
16 tahils = 1 kati (kan) = $1\frac{1}{3}$ lbs „
100 katis = 1 pikul (tam) = $133\frac{1}{3}$ lbs. „
40 pikuls = 1 koyan = $5333\frac{1}{3}$ lbs. „

Measures of Capacity.

1 pau or **quarter chupah** = 2 Imp. gills.
1 half chupah = 1 „ pint.
1 chupah = 1 „ quart.
1 gantang = 1 „ gallon.

SOUTH AFRICA.

The British Imperial system of weights and measures is used throughout British South Africa, but in the Cape Colony, British Bechuanaland, the Orange River Colony, the Transvaal and Rhodesia, a special system of land measure known as the *Cape System* is used :

Lineal Measure.

12 Cape inches = 1 Cape foot.
12 Cape feet = 1 rood.
425.94385 roods = 1 statute mile (1760 yards).
NOTE.—1 Cape foot = 1.033 British feet.

Square Measure.

144 square Cape inches = 1 square Cape foot.
144 square Cape feet = 1 square rood.
600 square roods = 1 morgen.

EGYPT.

Commercial Weight.

12 dirhems (drachms) = 1 okieh.
12 okiehs = 1 rotl or rottolo = 144 dirhems.
400 dirhems = 1 oke.
36 okes, 100 rotls = 1 kantar.
60 okes = 1 hamlah.
112 „ = 1 Alexandria kantar.
200 „ = 1 heml.

Jewellers' Weight.

4 kamhas = 1 kirat.
16 kirats = 1 dirhem.
24 „ = 1 mithkal.

Lineal Measure.

24 kirats = 1 diraâ baladi.

There are several diraâs (cubits or pikes) of different lengths in use, namely, the diraâ baladi or 'town' diraâ ; the diraâ mimari, used in building, etc. ; and the pike istambuli or Constantinople pike, used in measuring cloth.

The kassabah is the unit used in land surveying.

Square or Land Measure.

24 sohts	= 1 sahm.
4 sahms	= 1 danek.
2 daneks	= 1 habbah.
3 habbahs	= 1 kamel kirat.
24 kamel kirats	= 1 feddan (masri).
333⅓ square kassabahs	= 1 feddan (masri).

Measures of Capacity.

2 kirats	= 1 karrūbah.
2 karrūbahs	= 1 tūmnah.
2 tūmnahs	= 1 rūbaah.
2 rūbaahs	= 1 nesf kadah.
2 nesf kadahs	= 1 kadah.
2 kadahs	= 1 malwa.
2 malwas	= 1 rūb.
2 rūbs	= 1 kilah.
2 kilahs	= 1 webah.
6 webahs	= 1 **ardeb.**
8 ardebs	= 1 daribah.

7 rūbs	= 1 small fard.
14 „	= 1 large „

SECTION IV. CONVERSION TABLES.

In this section the scientific equivalents of the Metric and British Imperial weights and measures, together with the corresponding logarithms, are first given. These are followed by the Board of Trade legal equivalents of the Metric weights and measures, in which, as they are for use in trade, the same degree of accuracy is not required. The scientific equivalents of the United States and Metric weights and measures as published by the U.S. Bureau of Standards at Washington, and the shorter equivalents legalised in the United States by the Act of July 28, 1866, are also given. Then follow in the order named the Metric and British equivalents, together with the corresponding logarithms, of the Russian, Chinese, Japanese, British, Indian, Straits Settlements, Cape (S. Africa), and Egyptian weights and measures.

SCIENTIFIC EQUIVALENTS OF METRIC AND BRITISH IMPERIAL WEIGHTS AND MEASURES.

METRIC TO BRITISH IMPERIAL.

THE BOARD OF TRADE LEGAL EQUIVALENTS OF THE METRIC AND IMPERIAL WEIGHTS AND MEASURES FOR USE IN TRADE.*

METRIC TO BRITISH IMPERIAL.

Linear Measure.

1 millimetre (mm.) ($\frac{1}{1000}$ m.) = 0.03937 inch.
1 centimetre ($\frac{1}{100}$ m.) = 0.3937 „
1 decimetre ($\frac{1}{10}$ m.) = 3.937 inches.
1 metre (m.) = **39.370113 inches.** / **3.280843 feet.** / **1.0936143 yards.**
1 dekametre (10 m.) = 10.936 yards
1 hectometre (100 m.) = 109.36 „
1 kilometre (1000 m.) = 0.62137 mile.

Square Measure.

1 square centimetre = 0.15500 square inch.
1 square decimetre (100 square centimetres) = 15.500 square inches.
1 square metre (100 square decimetres) = 10.7639 square feet. / 1.1960 square yards.
1 are (100 square metres) = 119.60 „
1 hectare (100 ares or 10,000 square metres) = 2.4711 acres.

Cubic Measure.

1 cubic centimetre = 0.0610 cubic inch.
1 cubic decimetre (1000 cubic centimetres) = 61.024 cubic inches.
1 cubic metre (1000 cubic decimetres) = 35.3148 cubic feet. / 1.307954 cubic yards.

Measures of Capacity.

1 centilitre ($\frac{1}{100}$ litre) = 0.070 gill.
1 decilitre ($\frac{1}{10}$ litre) = 0.176 pint.
1 litre = **1.75980 pints.**
1 dekalitre (10 litres) = 2.200 gallons.
1 hectolitre (100 litres) = 2.75 bushels.

*These equivalents were legalised by Order in Council of May 19, 1898 (For the Scientific Equivalents see page 33.)

Weight.

Metric.	*Avoirdupois.*
1 milligram ($\frac{1}{1000}$ grm.)	= 0.015 grain.
1 centigram ($\frac{1}{100}$ grm.)	= 0.154 „
1 decigram ($\frac{1}{10}$ grm.)	= 1.543 grains.
1 gramme (1 grm.)	= 15.432 „
1 dekagram (10 grm.)	= 5.644 drams.
1 hectogram (100 grm.)	= 3.527 ounces.
1 kilogram (1000 grm.)	= **2.2046223 pounds or 15432.3564 grains.**
1 myriagram (10 kilog.)	= 22.046 pounds.
1 quintal (100 kilog.)	= 1.968 hundredweights.
1 tonne (1000 kilog.)	= 0.9842 ton.

Metric.	*Troy.*
1 gramme (1 grm.)	= 0.03215 ounce. 15.432 grains.

Metric.	*Apothecaries.*
1 gramme (1 grm.)	= 0.2572 drachm. 0.7716 scruple. 15.432 grains.

BRITISH IMPERIAL TO METRIC.

Linear Measure.

1 inch	= 25.400 millimetres.
1 foot (12 in.)	= 0.30480 metre.
1 yard (3 ft.)	= **0.914399 metre.**
1 fathom (6 ft.)	= 1.8288 metres.
1 pole ($5\frac{1}{2}$ yds.)	= 5.0292 „
1 chain (22 yds.)	= 20.1168 „
1 furlong (220 yds.)	= 201.168 „
1 mile (8 furlongs)	= 1.6093 kilometres.

Square Measure.

1 square inch	= 6.4516 square centimetres.
1 square foot (144 sq. ins.)	= 9.2903 square decimetres.
1 square yard (9 sq. ft.)	= 0.836126 square metre.
1 perch ($30\frac{1}{4}$ sq. yds.)	= 25.293 square metres.
1 rood (40 perches)	= 10.117 ares.
1 acre (4840 sq. yds.)	= 0.40468 hectare.
1 square mile (640 acres)	= 259.00 hectares.

Cubic Measure.

1 cubic inch = 16.387 cubic centimetres.
1 cubic foot (1728 cub. ins.) = 0.028317 cubic metre.
1 cubic yard (27 cub. ft.) = 0.764553 „

Measures of Capacity.

Imperial.	*Metric.*
1 gill	= 1.42 decilitres.
1 pint (4 gills)	= 0.568 litre.
1 quart (2 pints)	= 1.136 litres.
1 gallon (4 quarts)	= **4.5459631 litres.**
1 peck (2 gallons)	= 9.092 litres.
1 bushel (8 gallons)	= 3.637 dekalitres.
1 quarter (8 bushels)	= 2.909 hectolitres.

Apothecaries.	*Metric.*
1 minim	= 0.059 millilitre.
1 fluid scruple	= 1.184 millilitres.
1 fluid drachm (60 minims)	= 3.552 „
1 fluid ounce (8 drachms)	= 2.84123 centilitres.
1 pint	= 0.568 litre.
1 gallon (8 pints or 160 fluid oz.)	= **4.5459631 litres.**

Weight.

Avoirdupois.	*Metric.*
1 grain	= 0.0648 gramme.
1 dram	= 1.772 grammes.
1 ounce (16 drams)	= 28.350 „
1 pound (16 oz. or 7000 grains)	= **0.45359243 kilogram.**
1 stone (14 lbs.)	= 6.350 kilograms.
1 quarter (28 lbs.)	= 12.70 „
1 hundredweight (cwt.) (112 lb.)	= 50.80 „ / 0.5080 quintal.
1 ton (20 cwt.)	= 1.0160 tonnes or 1016 kilograms.

Troy.	*Metric.*
1 grain	= 0.0648 gramme.
1 pennyweight (24 grains)	= 1.5552 grammes.
1 troy ounce (20 pennyweights)	= 31.1035 „

Apothecaries.	*Metric.*
1 grain	= 0.0648 gramme.
1 scruple (20 grains)	= 1.296 grammes.
1 drachm (3 scruples)	= 3.888 „
1 ounce (8 drachms)	= 31.1035 „

COMPARISON OF UNITED STATES AND BRITISH IMPERIAL WEIGHTS AND MEASURES.

Lineal Measure.

United States and British Imperial Measures of length are practically the same, as 1 U.S. unit = 1.000002875 Imp. units of the same denomination, a difference of 2.875 in a million.

Square Measure.

1 U.S. unit = 1.00000575 Imp. units, a difference of 5.75 in a million.

Cubic Measure.

1 U.S. unit = 1.000008625 Imp. units, a difference of 8.625 in a million.

Measures of Capacity.

Liquid.

1 U.S. liquid gallon	= 0.83270 Imp. gallon.	log = 9.9204898
1 Imp. gallon	= 1.20091 U.S. liquid gallons.	log = 0.0795102

Dry.

1 U.S. bushel	= 0.96897 Imp. bushel.	log = 9.9863111
1 Imp. bushel	= 1.03202 U.S. bushels.	log = 0.0136889

Weights.

No difference.

EQUIVALENTS OF UNITED STATES AND METRIC WEIGHTS AND MEASURES AS PUBLISHED BY THE U.S. BUREAU OF STANDARDS, WASHINGTON.*

Measures of Length.

Basis: 1 meter = 39.37 inches.

1 U.S. inch	= 25.4000508 millimeter.	log = 1.4048346
1 U.S. foot	= 0.3048006096 meter.	log = 9.4840158
1 U.S. yard	= 0.9144018288 meter.	log = 9.9611371
1 U.S. mile	= 1.609347219 kilometers.	log = 0.2066497
1 millimeter	= 0.03937 U.S. inch.	log = 8.5951654
1 meter	= 3.28083 U.S. feet.	log = 0.5159842
1 kilometer	= 0.6213699495 U.S. mile.	log = 9.7933503

* *Tables of Equivalents*, Washington, Nov. 1906. The U.S. *legal* equivalents are given on page 40.

Measures of Area.

1 U.S. acre = 0.404687261 0 hectare.	log = 9.6071196
1 hectare = 2.471043930 U.S. acres.	log = 0.3928804

Measures of Volume.

1 U.S. cubic yard = 0.7645594453 cubic meter.	log = 9.8834113
1 cubic meter = 1.307942772 U.S. cubic yards.	log = 0.1165887

Measures of Capacity.

Liquid.

Basis: 1 U.S. liquid gallon = 231 cubic inches, and 1 cubic decimeter = 1 liter.

1 U.S. liquid gallon = 3.785434497 liters.	log = 0.5781157
1 liter = 0.2641704673 U.S. liquid gall.	log = 9.4218843

Dry.

Basis: 1 U.S. bushel = 2150.42 cubic inches, and 1 cubic decimeter = 1 liter.

1 U.S. bushel = 0.3523928160 hectoliter.	log = 9.5470270
1 hectoliter = 2.837742299 U.S. bushels.	log = 0.4529730

Weights.

Basis: 1 avoirdupois pound = 453.5924277 grams.

The equivalents are therefore the same as those given for British Imperial Weights on pages 33 and 34.

THE EQUIVALENTS OF THE METRIC WEIGHTS AND MEASURES LEGALISED IN THE UNITED STATES BY THE ACT OF JULY 28th, 1866.*

Measures of Length.

Metric denominations and values.	Equivalents in denominations in use.
Myriameter - - 10,000 meters.	6.2137 miles.
Kilometer - - 1,000 meters.	0.62137 miles or 3280 feet and 10 inches.
Hectometer - - - 100 meters.	328 feet and 1 inch.
Dekameter - - - 10 meters.	393.7 inches.
Meter - - - - - - 1 meter.	39.37 inches.
Decimeter - - $\frac{1}{10}$ of a meter.	3.937 inches.
Centimeter - - $\frac{1}{100}$ of a meter.	0.3937 inch.
Millimeter - - $\frac{1}{1000}$ of a meter.	0.0394 inch.

*(The scientific equivalents published by the Bureau of Standards, Washington, are given on page 39.)

Measures of Surface.

Metric denominations and values.	Equivalents in denominations in use.
Hectare - - - 10,000 square meters.	2.471 acres.
Are - - - - - 100 square meters.	119.6 square yards.
Centiare - - - - - 1 square meter.	1,550 square inches.

Measures of Capacity.

Metric denominations and values.			Equivalents in denominations in use.	
Names.	Number of liters.	Cubic Measure.	Dry Measure.	Liquid or Wine Measure.
Kiloliter or stere	1,000	1 cubic metre	1.308 cubic yards	264.17 gallons.
Hectoliter	100	$\frac{1}{10}$ of a cubic meter	2 bushels and 3.35 pecks	26.417 gallons.
Dekaliter	10	10 cubic decimeters	9.08 quarts	2.6417 gallons.
Liter	1	1 cubic decimeter	0.908 quart	1.0567 quarts.
Deciliter	$\frac{1}{10}$	$\frac{1}{10}$ of a cubic decimeter	6.1022 cub. inches	0.845 gill.
Centiliter	$\frac{1}{100}$	10 cubic centimeters	0.6102 cubic inch	0.338 fluid ounce.
Milliliter	$\frac{1}{1000}$	1 cubic centimeter	0.061 cubic inch	0.27 fluid dram.

Weights.

Metric denominations and values.			Equivalents in denominations in use.
Names.	Number of grams.	Weight of what quantity of water at maximum density.	Avoirdupois Weight.
Millier or tonneau	1,000,000	1 cubic meter	2204.6 pounds.
Quintal - - - -	100,000	1 hectoliter	220.46 pounds.
Myriagram - - -	10,000	10 liters	22.046 pounds.
Kilogram or kilo -	1,000	1 liter	2.2046 pounds.
Hectogram - - -	100	1 deciliter	3.5274 ounces.
Dekagram - - -	10	10 cubic centimeters	0.3527 ounce.
Gram - - - -	1	1 cubic centimeter	15.432 grains.
Decigram - - -	$\frac{1}{10}$	$\frac{1}{10}$ of a cub. centimeter	1.5432 grains.
Centigram - - -	$\frac{1}{100}$	10 cubic millimeters	0.1543 grain.
Milligram - - -	$\frac{1}{1000}$	1 cubic millimeter	0.0154 grain.

TABLE OF RATES OF EXCHANGE FOR MONEY.

Country.	Gold Import Point.	Mint Parity.	Gold Export Point.
France, Belgium, Italy, Switzerland,	Francs 25.35	Fr. 25.22	Fr. 25.09
Holland, - - -	Florins 12.15	Fl. 12.10¾	Fl. 12.04
Germany, - -	Marks 20.51	M. 20.43	M. 20.35
Austria-Hungary, -	Kronen 24.20	Kr. 24.02	Kr. 23.90
Scandinavia, - -	Kroner 18.30	Kr. 18.16	Kr. 18.02
Russia, - - -	Roubles 9.6 (1 Rr. = 25d.)	Rs. 9.459 (1 Rs. = 25⅜d.)	Rs. 9.366 (1 Rs. = 25⅝d.)
United States of America,	Dollars 4.90	$ 4.8665	$ 4.84
British India, -		Rupees 15 (1 ₹ = 1s. 4d.)	₹ 14.657 (1 ₹ = 1s. 4⅜d.)
Egypt, - - -	Piastres 97⅞	Piastres 97½	Piastres 97⅛

The above table* gives the value of £1 sterling in the currencies of the following countries: France, Belgium, Italy, Switzerland, Holland, Germany, Austria-Hungary, Scandinavia, Russia, United States of America, British India and Egypt.

The middle column gives the exchange at mint parity, *i.e.* the actual gold value of the foreign currency in comparison with the pound sterling, while the other columns show the extremes of fluctuation in the rate of exchange *in normal times*. In the left-hand column are the rates of exchange at which in sending remittances *to* London it would be more profitable to send gold than to purchase drafts; while in the right-hand column are the rates at which in remitting *from* London it would be more profitable to buy gold and send it abroad than to purchase drafts.

* Kindly compiled by Mr. F. Moshack of the Deutsche Bank.

PART II. DATA RELATING TO FORCE AND ENERGY.

SECTION I. MECHANICAL UNITS.

Force.—The British unit of force is termed the *poundal*; it is that force which, acting on a mass of 1 lb. for one second, gives it a velocity of one foot per second. On the C.G.S. (centimetre gramme-second) system the unit of force is the *dyne*, which may be defined as that force which, acting on a mass of 1 gramme, gives it a velocity of 1 centimetre per second.

1 poundal = 13825 dynes.

Gravity.—The apparent acceleration (or increase of velocity per unit of time) of a body falling freely under the influence of gravity in vacuo (g) varies according to locality. The value of g in C.G.S. units is 981.17 centimetres per second at Greenwich, 980.94 at Paris, 981.25 at Berlin, 978.10 at the equator and 983.11 at the poles. The mean value adopted by the International Bureau of Weights and Measures for latitude 45° at sea-level is 980.665.* In British measure the value of g for London at sea-level is about 32.19 feet per second.† The length of the seconds pendulum for the same places is as follows:

Greenwich, 99.413 cm.; Paris, 99.390 cm.; Berlin, 9.422 cm.; equator, 99.103 cm.; and the poles, 99.610 cm.

Work.—The British unit of work is the *foot-poundal*. It is the work done by a force of 1 poundal acting over a distance of 1 foot. Work is also expressed in *foot-pounds*, the unit in this case being the work done when a body moves through 1 foot against a resistance of gravity equal to 1 lb.

1 foot-pound = g poundals.

* *Comptes Rendus des séances de la Troisième Conférence générale des Poids et Mesures à Paris*, 1901, p. 70.

† This is the value adopted by the Board of Trade Standards Department.

On the C.G.S. system the unit of work is the *erg*. It is the work done by a force of 1 dyne acting over a distance of 1 centimetre.

1 foot poundal = 421401 ergs.

1 foot-pound = 1.356×10^7 ergs (g being taken as 981).

Power.—The British unit of power or rate of doing work is the *horse-power*. It is equivalent to 33,000 foot-pounds per minute or 550 foot-pounds per second. The French unit—the *force de cheval*—is defined as 75 kilogram-metres per second. One "force de cheval" equals 0.9863 horse-power or 542.48 foot-pounds per second, and conversely 1 horse-power = 1.01385 "force de cheval."

On the C.G.S. system the unit of power is 1 erg per second.

Taking g as equal to 981, we have

1 horse-power = 7.46×10^9 ergs per second.

1 force de cheval = 7.36×10^9 ergs per second.

SECTION II. ELECTRICAL UNITS.

Resistance.—The unit of electrical resistance is the *ohm.** It is defined by the Board of Trade † as "the resistance offered to an unvarying electric currrent by a column of mercury, at the temperature of melting ice, 14.4521 grammes in mass of a constant cross sectional area and of a length of 106.3 centimetres." For practical purposes, however, the Board of Trade use as the standard of electrical resistance the resistance between the copper terminals of a coil of insulated wire of platinum alloy to the passage of an unvarying electrical current, at a temperature of 15.4 C. This standard is marked "Board of Trade Ohm Standard, verified 1894,"‡ and is deposited at the Board of Trade Standardising Laboratory. The ohm has the value of 10^9 absolute units on the C.G.S. system.

Current.—The unit of current is the *ampere*. It is defined by

* The terms *ohm* and *volt* were first suggested by Sir C. Bright and Mr. Latimer Cross; together with *ampere*, *coulomb* and *farad*, they were adopted by an International Congress which met in 1881. The use of the terms *joule*, *watt* and *henry* was recommended by the Chamber of Delegates at the Chicago Exhibition in 1893.

† *Final Report of the Electrical Standards Committee*, 1894, p. 10.

‡ This Standard was legalised by Order in Council of her late Majesty Queen Victoria of Aug. 23, 1894.

the Board of Trade as the electric current, which, when passed through a neutral solution containing 15 per cent. of nitrate of silver, deposits silver at the rate of 0.001118 of a gramme per second.* For practical purposes the standard used by the Board of Trade is the current "which is passing in and through the coils of wire forming part of the instrument marked 'Board of Trade Ampere Standard, verified 1894' when in reversing the current in the fixed coils the change in the forces acting upon the suspended coil in its righted position is exactly balanced by the force exerted by gravity in Westminster upon the iridio-platinum weight marked *A* and forming part of the said instrument."† The ampere has the value of $\frac{1}{10}$ or 10^{-1} C.G.S. units.

1 milli-ampere = $\frac{1}{1000}$ ampere.

1 kilo-ampere = 1000 amperes.

Pressure.—The unit of electrical pressure is the *volt*. It is "the pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere, and is represented by 0.6974 of the electrical pressure at a temperature of 15° C. between the poles of the voltaic cell, known as Clark's cell."‡ For practical purposes the unit is measured by a particular instrument marked "Board of Trade Volt Standard, verified 1894," deposited at the Board of Trade Standardising Laboratory. On the C.G.S. system the volt has the value of 10^8.

Quantity.—The unit of quantity is the *coulomb*. It is the quantity of electricity which in one second of time passes any part of a circuit in which the current has the strength of one ampere. Therefore 1 coulomb equals 1 ampere-second.

On the C.G.S. system the coulomb has the value of 10^{-1}.

$$1 \text{ micro coulomb} = \frac{1}{1{,}000{,}000} \text{ or } 10^{-6} \text{ coulomb.}$$

Capacity.—The unit of capacity is the *farad*. It is the capacity of a condenser charged to the potential of 1 volt by 1 coulomb of electricity. On the C.G.S. system the farad has the value of 10^{-9}.

$$1 \text{ micro-farad} = \frac{1}{1{,}000{,}000} \text{ or } 10^{-6} \text{ farad.}$$

* *Final Rep. of the Elect. Stand. Comm.*, 1894, p. 10.

† *Loc. cit.*, p. 11.

‡ *Loc. cit.* Clark's cell consists of zinc or an amalgam of zinc with mercury and of mercury in a neutral saturated solution of zinc sulphate and mercurous sulphate in water, prepared with mercurous sulphate in excess.

Work.—The unit of work is the *joule*. It is equivalent to the energy disengaged as heat in one second by a current of 1 ampere flowing through a resistance of 1 ohm, or in other words, under an electro-motive force of 1 volt.

1 joule = 10^7 ergs or absolute units of work.

Power.—The unit of power or rate of doing work is the *watt*. It is the work done at the rate of 1 joule per second. In other words, the watt represents the energy contained in a current of one ampere flowing under an electro-motive force of 1 volt. On the C.G.S. system the watt represents 10^7 ergs per second. The practical unit of work is the *kilowatt*.

1 kilowatt = 1000 watts
= 1.34 horse-power.
1 horse-power = 746 watts or .746 kilowatt.

The commercial or Board of Trade unit is the *kilowatt-hour*. It is defined by the Board of Trade as "the energy contained in a current of one thousand amperes flowing under an electro-motive force of one volt during one hour."

Induction.—The unit of induction is the *henry*. It is the induction in a circuit when the electro-motive force induced in this circuit is one volt, while the inducing current varies at the rate of one ampere per second.

On the C.G.S. system the henry has the value of 10^9.

Table of Horse Power and Kilowatts in terms of one another.

1 Horse-power	= 0.746	Kilowatt.		1 Kilowatt	= 1.340	Horse power

9	„ = 6.714	„		9	„ = 12.064	„	

SECTION III. THERMAL UNITS.

The **British thermal unit** is the amount of heat required to raise 1 pound of water through 1 degree Fahrenheit. The thermal capacity of water varies slightly with the temperature; but the standard temperature of the water at which the unit should be defined has not yet been fixed by convention.

The **French thermal unit** is the *therm* or *gramme-degree.* It has also been termed the *minor calorie.* It is the quantity of heat required to raise 1 gramme of water through 1 degree Centigrade. It is sometimes defined as the amount of heat required to raise 1 gramme of water from 0° C. to 1° C., or as the one-hundredth part of the heat required to raise one gramme of water from 0° to 100° C.

The *major calorie* is the quantity of heat required to raise 1 kilogramme of water through 1 degree Centigrade.

1 major calorie = 1000 therms.

1 therm or minor calorie = 0.00396832 British thermal unit (log = 7.5986067).

1 British thermal unit = 251.99579 therms (log = 2.4013933).

The **capacity for heat** (or **thermal capacity**) of a substance is the quantity of heat required to raise the temperature of that substance 1 degree (Centigrade or Fahrenheit, according to the units in use).

The capacity for heat of water can be expressed thus:

1 calorie (therm) = 4.180 joules at 20° C.*

The **specific heat** of a substance is the ratio of the quantity of heat required to raise the temperature of a given mass of any substance one degree to the quantity of heat required to raise the temperature of an equal mass of water one degree (Glazebrook).

The **latent heat of fusion** is the quantity of heat required to change 1 gramme (or 1 lb.) of a substance from the solid to its liquid form without raising its temperature. The latent

* Preston's *Theory of Heat*, 2nd edition, London, 1904, p. 322.

heat of fusion of ice is 80 therms (Bunsen) or 144 British thermal units.

The **latent heat of vaporization** of a liquid is the amount of heat required to change 1 gramme (or 1 lb.) of the liquid into vapour without raising its temperature. The latent heat of vaporization of water is 537 therms, or 967 British thermal units.

The **evaporative power** or **calorific value** of a fuel is the number of pounds of water evaporated at 212° F. by the combustion of 1 lb. of that fuel. It may be expressed in British thermal units by multiplying the number of pounds of water evaporated at 212° F. by 967 (the latent heat of vaporization of water).

The mechanical equivalent of heat. The symbol J is used to designate the number of units of work necessary to generate one unit of heat when the unit is all spent in generating heat. Prof. Rowland's experiments show that at 20° C.*

$$J = 427.5 \text{ gramme-metres}$$
$$= 779 \text{ foot-pounds},$$

i.e. the work done in raising $\left\{\begin{matrix}1 \text{ gramme} \\ 1 \text{ pound}\end{matrix}\right\}$ through $\left\{\begin{matrix}427.5 \text{ metres} \\ 779.0 \text{ feet}\end{matrix}\right\}$ will, if spent in friction, raise the temperature of $\left\{\begin{matrix}1 \text{ gramme} \\ 1 \text{ pound}\end{matrix}\right\}$ of water 1 degree $\left\{\begin{matrix}\text{Centigrade} \\ \text{Fahrenheit}\end{matrix}\right\}$.

* Preston's *Theory of Heat*, London, 1904, p. 45.

To convert Fahrenheit degrees to Centigrade or Réaumur, subtract 32 and multiply the difference by $\frac{5}{9}$ or $\frac{4}{9}$ respectively. To convert Centigrade or Réaumur to Fahrenheit, multiply by $\frac{9}{5}$ or $\frac{9}{4}$, as the case may be, and add 32 to the product. To convert Centigrade to Réaumur, multiply Centigrade degrees by $\frac{4}{5}$; and to convert to Centigrade, multiply Réaumur degrees by $\frac{5}{4}$. To obtain absolute temperature, add 273° to the Centigrade scale.

Photometric Standards.

The British unit of light, the *candle power*, as originally defined,* is the illuminating power of a sperm candle $\frac{1}{8}$ inch in diameter (6 to the pound) burning 120 grains per hour. The Harcourt 10-candle power pentane lamp, however, is accepted by the Gas Referees as representing ten British candles.

The French unit, the *Carcel*, is the illuminating power of a lamp burning 42 grammes of pure colza oil per hour.

The German unit, the *Hefner*, is the illuminating power of the Hefner-Alteneck lamp, burning amyl-acetate with a cylindrical wick 8 mm. in diameter and a flame-height of 40 mm.

The International Congress, held at Paris in April, 1884, proposed the illuminating power of a square centimetre of molten platinum at the temperature of solidification as a unit; but at the Congress held in 1890 the 20th part of this unit was adopted as the international standard unit, under the name of the *decimal candle.*

The following relations between these lamps have been established by tests made in the German Reichsanstalt, at the instance of the International Committee on Photometry. The tests were made in air containing 8.8 litres of aqueous vapour per cubic metre of dry air, and under a barometric pressure of 760 mm. †

Name of Lamp.	Harcourt Units (=10 British Candles).	Carcel Units.	Hefner Units.	Decimal Candles.

PART III. DATA RELATING TO WATER.

SECTION I. CONSTANTS.

Relation of Weight and Volume.

THE Imperial Gallon is the volume of 10 avoir. lbs. of distilled water weighed *in air* against brass weights, with the water and air at a temperature of 62° Fahr., under a barometric pressure of 30 inches. The following constants apply to water under these conditions: *

Weight of 1 cubic inch of water at 62° F.

= 252.3253 grains.	log = 2.4019608
= .0360465 lb.	log = 8.5568628
= .00360465 Imp. gallon.	log = 7.5568628

Weight of 1 cubic foot of water at 62° F.

= 62.2883 lbs.	log = 1.7944065
= 6.22883 Imp. gallons.	log = 0.7944065

Volume of 1 short ton (2000 lbs.) of water at 62° F.

= 32.1088 cub. feet.	log = 1.5066235

Volume of 1 long ton (2240 lbs.) of water at 62° F.

= 35.9618 cub. feet.	log = 1.5558415

1 Imperial gallon

= 277.420 cub. inches.	log = 2.4431372
= .160544 cub. foot.	log = 9.2055935

A column of water 1 foot high at 62° F. exerts a pressure of .43$\dot{2}\dot{5}$ lb. per sq. inch: log = 9.6360419.

A pressure of 1 lb. per sq. in. is exerted by a column of water at 62° F., 2.31184 feet high: log = 0.3639581.

The Litre is the volume of a kilogram of distilled water weighed *in vacuo* at its temperature of maximum density

* See page 7.

(4° C. or 39°.2 F.). By means of the equivalents given on page 33, and the weight of a cubic decimetre of water on page 4, we find that

1 gramme per cubic centimetre = 62.4278 lbs. per cubic foot; and the weight *in vacuo* of 1 cubic decimetre of distilled water at 4° C. = .999974 kilogram.

Therefore the weight *in vacuo* of 1 cubic foot of distilled water at 4° C. = 62.4278 × .999974 = 62.4262 lbs.

Constants used in the measurement of flow.

1 cusec* of water at 62° F.

= 60 cubic feet per minute	log = 1.7781513
= 3600 cubic feet per hour	log = 3.5563025
= 86400 cubic feet per day of 24 hours	log = 4.9365137
= 6.22883 Imp. gallons per second	log = 0.7944065
= 373.73 Imp. gallons per minute	log = 2.5725578
= 22423.8 Imp. gallons per hour	log = 4.3507090
= 538170.9 Imp. gallons per day of 24 hours	log = 5.7309202
= 7.48026 U.S. gallons per second	log = 0.8739167
= 448.816 U.S. gallons per minute	log = 2.6520680
= 26928.94 U.S. gallons per hour	log = 4.4302192
= 646294.4 U.S. gallons per day of 24 hours.	log = 5.8104304

1 cubic foot per minute of water at 62° F.

= 60 cubic feet per hour	log = 1.7781513
= 1440 cubic feet per day of 24 hours	log = 3.1583625
= 6.22883 Imp. gallons per minute	log = 0.7944065
= 373.73 Imp. gallons per hour	log = 2.5725578
= 8969.54 Imp. gallons per day of 24 hours	log = 3.5927700
= 7.48026 U.S. gallons per minute	log = 0.8739167
= 448.816 U.S. gallons per hour	log = 2.6520680
= 10771.58 U.S. gallons per day of 24 hours.	log = 4.0322792

The *miner's inch* is usually taken to be a flow of 1.5 cubic feet per minute.

*'Cusec' is the abbreviation of 'cubic foot per second,' commonly used in referring to the flow of water.

The volume in cubic centimetres at various temperatures from 0° to 35° Centigrade of a cubic centimetre of distilled water at 4° C.*

For 16⅔° C. (62° F.) the volume is 1.001136.

* This table was compiled by Landolt and Börnstein from determinations made by Thiesen, Scheel and Marek. It is taken from the *Smithsonian Physical Tables*, Washington, 1906.

SECTION II. MEASUREMENT OF THE FLOW OF WATER.

In measuring the flow of a stream by means of a rectangular-notched weir (Fig. 1), the length of the notch should be at least three times the depth of water on the sill. Air should have free access to the space behind the falling sheet of water, and the sill should be carefully levelled.

FIG. 1.

End contraction, which occurs when the weir at each end of the notch projects into the approach channel, diminishes the discharge. The contraction is complete, that is as great as it can be, when the distance from the end of the notch to the side of the approach channel is equal to the depth of water on the sill. If the width of the notch be not less than three times the depth of water on the sill, a complete end contraction diminishes the *effective width* of the notch by an amount equal to one-tenth of the depth of the water on the sill. If contraction occurs at both ends of the notch, the effective width will of course be diminished by twice the above amount.

The notches of weirs should be made preferably in thin sheet iron; if in wood, the *downstream* side should be bevelled off so as to present a smooth sharp edge to the water on the upstream side. In a wooden weir two inches thick, a notch cut with square edges (without bevel) gives a discharge 15½ per cent. less than that of a similar notch in thin sheet iron. The weir can be made of deal boards with the notch cut in the wood, or a thin sheet iron plate with the notch can be attached to the topmost board. The weir site should be chosen at a point where the stream will be dammed back for at least six feet. The weir should be let into the banks and should be firmly fixed into

position and made water-tight by means of clay. Unless a proper approach channel is provided, the ends of the notch should be far enough from the banks to ensure complete end contraction, which must then be allowed for. No measurements should be made until the normal flow of the stream is passing through the notch. The depth of the water must not be measured on the notch itself, but from the sill to the surface of the still water at a point some six feet above the weir, a level being employed.

For gauging a small flow, a right-angled triangular notch (Fig. 2) will be found more convenient. It is the only form of notch in which the periphery always bears the same ratio to the cross-sectional area of the stream flowing through it.

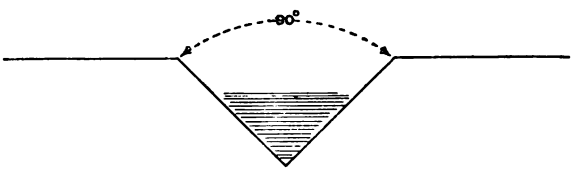

FIG. 2.

On pages 72 and 73 are tables giving the discharges through each form of notch for a varying depth of water. In the first table, which is for a rectangular-notched weir in thin sheet iron,

Q = Discharge in 'cusecs' (cubic feet per second).

H = Depth in feet of water, measured from sill of notch to surface of still water above the weir.

L = Width in feet of notch.

$Q = 3.33\, LH\sqrt{H}$ (Francis' formula).

The table is calculated for a notch 1 foot in width, and no deduction has been made for end contraction which is hardly appreciable when H is less than $\frac{L}{10}$. In using the table, multiply Q by the *effective* width of the notch in feet.

[Table

Table for Estimating Discharge of Water through a Rectangular-notched Weir, without end contraction.

Table for Estimating Discharge of Water through a Right-angled Triangular Notch in Thin Sheet Iron.

Q = Discharge in cubic feet per minute.

n = Head in inches measured from bottom of notch to surface of still water above weir.

$Q = .306\sqrt{n^5}$ (Thomson's formula).

The Table is calculated for heads from 1 to 15 inches, increasing by decimal parts of an inch. No deduction has to be made for end contraction.

n	Q	n	Q	n	Q	n	Q
1	.306	4.6	13.886	8.2	58.935	11.8	146.329

SECTION III. STORAGE OF WATER BY SMALL DAMS FOR MINING AND IRRIGATION PURPOSES.

Dimensions for Small Earthen Dams.

Mr. A. M. Strange* recommends the following dimensions for small earthen dams :

Maximum height of Dam above Ground Level.	Height of top of Dam above High Flood Level.	Top Width.	Upstream (or Reservoir side) Slope.	Downstream Slope.
	Feet.	Feet.	Ratio of Horizontal Width to Vertical Height.	
1. Under 8 feet, - - -	3	6	1½ to 1	1 to 1
2. From 8 to 15 feet, - -	4	8	2 to 1	1½ to 1

The above dimensions only apply when the soil is of a suitable nature and the wall is well and compactly made on a site from which all vegetation has first been removed. A clay core is usually effective in preventing leakage. The by-wash or waste weir channel and the upstream face of the wall should be "pitched" with stone. The high flood level is the level of the maximum discharge over the waste weir in time of flood.

Flood Discharge Allowances for Waste Weir Channels.

The following table gives what should prove quite safe allowances for the widths of waste weirs required for ordinary small catchment or drainage areas.

TABLE OF WASTE WEIR CHANNELS.

For catchment areas up to	Discharge per 250 acres of catchment	Width of Waste Weir Channels required per 250 acres of catchment.	
		1 ft. deep.	2 ft. deep.
1	2	3	4
Acres.	Cubic feet per second.	Feet.	Feet.
640	75	31.5	10.3
1280	70	29.5	9.6
1920	66	27.7	9.06
2560	62	26.0	8.5
3200	59	24.8	8.0

Note. In regard to the catchment area, take the figure entered in column 1, which is the nearest greater than the one under consideration, and use the corresponding figures in columns 2–4. For

* *Bulletin No. 1, Irrigation Dept., Transvaal*, Pretoria, 1905.

catchments above 3200 acres (5 square miles), the discharges (*vide* column 2) should be reduced gradually.

Example. A catchment area of 1000 acres may be expected to produce a high-flood discharge of (4×70=)280 cubic feet per sec., which would require a waste weir channel flowing 1 foot deep to be (4×29.5=)118 feet wide; or a channel flowing 2 feet deep to be (4×9.6=)38.4 feet wide.

The tables on pp. 76, 77 will be found of use in calculating the amount of earthwork contained in the wall. The height of the wall should be taken at each change of slope in the contour of the site, also the distance between each height measurement. Then half the sum of the areas of two adjoining cross-sections multiplied by the distance *in feet* between them gives the contents in cubic feet of that portion of the wall.

The Relation of Rainfall to Irrigation.

1 inch rainfall over 1 acre = 3630 cubic feet of water.
2 " " " = 7260 " " "
2.5 " " " = 9075 " " "
3 " " " = 10890 " " "
4 " " " = 14520 " " "
7.13 " " " = 25882 " " "

Therefore, water flowing at the rate of 1 cubic foot per second for 30 days (1 month) is equivalent to

a rainfall of 1 inch per month on 713 acres.
" " 2 " " " 356 "
" " 2.5 " " " 285 "
" " 3 " " " 237 "
" " 4 " " " 178 "
" " 7.13 " " " 100 "

It will be seen from the above table that a rainfall of 2½ inches per month corresponds to the flow of 1 cubic foot per second (1 cusec) over 285 acres.

This is termed an 'irrigating duty' of 285 acres per cusec, which means that one cubic foot of water per second has to irrigate 285 acres.

The irrigating duty of water varies according to the climate, the nature of the soil, the class of crop and the method of cultivation.

An irrigating duty of

285 acres per cusec = 9075 cub. ft. per acre per month.
250 " " = 10345 " " "
200 " " = 12931 " " "
150 " " = 17242 " " "
100 " " = 25863 " " "

Tables for Calculation of Cubic Contents of Earthen Dam Embankments.*

Decimals of a Foot.	0·0	0·1	0·2	0·3	0·4	0·5	0·6	0·7	0·8	0·9

A general rule for dimensions of dams over 16 feet high is:

Top width = ½ the maximum height.
Upstream slope = 3 to 1.
Downstream slope = 2 to 1.

The level of the waste weir should be from 5 to 6 feet below the level of the top of the wall.

SECTION IV. FLOW OF WATER IN PIPES.

General Laws.—1. When the diameter and length are constant, the discharge varies directly as the square root of the head. Conversely, the head is directly as the square of the discharge.

2. When the head and length are constant, the discharge is directly as the 2.5th power of the diameter. Conversely, the diameter will vary as the 2.5th root of the discharge.

3. When the discharge and length are constant, the head will be inversely as the 5th power of the diameter. Conversely, the diameter will be inversely as the 5th root of the head.

4. When the head and diameter are constant, the discharge will be inversely as the square root of the length. Conversely, the length varies as the square of the discharge.

5. When the discharge and diameter are constant, the head is directly and simply as the length.

The hydraulic mean gradient corresponds to a straight line drawn between the points of intake and delivery of a pipe. No loss of effect will arise from the pipe following the contour of the ground as long as it keeps below the hydraulic mean gradient. If the pipe be carried over a hill which is above the hydraulic mean gradient but below the level of the intake, the first section, having a low head, must be of a greater diameter than the subsequent section, which has a greater head.

The sine of slope of the hydraulic mean gradient is the head divided by the length of the pipe.

The hydraulic mean depth, or *mean radius*, is the cross-sectional area of the water divided by the length of the wetted perimeter of the pipe or channel; in a circular pipe running full it is equal to one-fourth the diameter ($\frac{d}{4}$).

Except under considerable pressure, flowing water does not entirely fill the pipe, and yet if it be more than three-quarters full, the discharge is but slightly less than if it were full. This is due to the fact that the full circle does not give the maximum discharging velocity, which is attained when the pipe is filled to the level of the chord of an arc of $78\frac{1}{2}°$. This gives an increase over the full circle of $9\frac{1}{2}$ per cent. in velocity, and

over $2\frac{1}{2}$ per cent. in discharge. The mean radius can therefore be safely taken as equal to $\frac{d}{4}$ when the pipe is more than three-quarters full.

Discharge in cubic feet per second = cross-sectional area of water in square feet × mean velocity in feet per second.

Cross-Sectional Areas and Capacities of Cylindrical Pipes of Various Diameters.

D = the diameter of the pipe in inches.

A = the cross-sectional area of the pipe in square feet; or the number of cubic feet in a length of 1 foot.

D	A	D	A	D	A

Velocity.—Let v = the mean velocity in feet per second.

r = the hydraulic mean depth.

s = the sine of slope.

Then $v = C\, r^{\frac{2}{3}}\, s^{\frac{1}{2}}$.

Or v = the cube root of the square of r × the square root of s × the value of C in the table. C is a coefficient which varies according to the smoothness of the interior surface of the pipe or conduit; but which is not appreciably affected by differences in slope or diameter.

Values of C.

Asphalted wrought-iron pipe = 170.
Plain " " " = 160.
Cast-iron pipe, new, = 130.
" " in service, = 104.
Lap-riveted pipe, = 115.
Brick conduits, = 110.

Loss of Head in Friction

(1) is proportional to the length of the pipe,

(2) is increased by roughness of the interior surface of the pipe,

(3) decreases as the diameter of the pipe is increased,

(4) increases nearly as the square of the velocity,

(5) is independent of the pressure of the water.

These five laws may be expressed by the formula:

$$h' = f\frac{l}{d}\frac{v^2}{2g}$$

where h' = loss of head in friction in feet.

l = length of pipe in feet.

d = diameter of pipe in feet.

v = mean velocity in feet per second.

g = acceleration due to gravity = 32.19 feet per second.

f = a variable constant (see table).

$\frac{v^2}{2g}$ = velocity head due to mean velocity of flow.

Values of f. (Mansfield Merriman.*)

* *Treatise on Hydraulics*, New York, 1904, p. 559.

Loss of Head in Curvature.

Let h'' = loss of head in curvature in feet.
R = radius of curve in feet.
f_1 = a variable coefficient.

Then $h'' = f_1 \frac{l}{d} \frac{v^2}{2g}$

Values of f_1.

$\frac{R}{d}$	20	10	5	3	2	1.5	1.0
f_1	.004	.008	.016	.030	.047	.072	.184

In laying down a permanent pipe-line, allowance should be made for incrustation, which reduces the effective diameter of a pipe by from $\frac{1}{2}$ to $1\frac{1}{2}$ inches. A small reduction in the size of a pipe makes a large reduction in the discharge. $\frac{1}{10}$th increase in the diameter gives an increase of about 25%, and $\frac{1}{6}$th about 50% in the discharge.

PART IV. DATA RELATING TO AIR AND STEAM.

SECTION I. AIR.

THE coefficient of expansion of air at constant pressure per 1 degree Centigrade $= \frac{1}{273}$ or .00366957 (Jolly).

The standard height of a mercury barometer is 29.922 inches or 760 millimetres.

The standard atmospheric pressure at sea-level and standard barometric pressure

= 14.706 lbs. per square inch = 1 atmosphere

= 1033.3 grammes per square centimetre.

The average atmospheric pressure at $\frac{1}{4}$ mile above sea-level = 14.02 lbs. per sq. in.

,,	,,	at $\frac{1}{2}$	mile	above	sea-level	= 13.33	,,	,,
,,	,,	$\frac{3}{4}$	,,	,,	,,	= 12.66	,,	,,
,,	,,	1	,,	,,	,,	= 12.02	,,	,,
,,	,,	$1\frac{1}{4}$	,,	,,	,,	= 11.42	,,	,,
,,	,,	$1\frac{1}{2}$	,,	,,	,,	= 10 88	,,	,,
,,	,,	2	,,	,,	,,	= 9.80	,,	,,

The pressure of one atmosphere (or 14.706 lbs. to the square inch) = that of a column of water at 62° F. 34 feet in height. This is therefore the maximum theoretical lift of a pump at sea-level.

One lb. of dry air at 0° C. (32° F.) has a volume of 12.39 cub. ft.

,, ,, ,, 15° C. (60° F.) ,, ,, 13.072 ,,

One cubic foot of dry air at 0° C. (32° F.) weighs .0807 lb.

,, ,, ,, ,, 15° C. (60° F.) ,, .0765 ,,

One gramme of dry air at 0° C. has a volume of 773.3 cm.^{3}

One cubic centimetre of dry air at 0° C. weighs .001293 gramme.

Pressure of Columns of Mercury and Water.*

Metric and British measures. Correct at 0° C. for mercury and 4° C. for water.

PART V. DATA SPECIALLY RELATING TO MINING.

SECTION I. DENSITY AND OTHER PHYSICAL PROPERTIES OF VARIOUS MINERAL SUBSTANCES, ORES, METALS, ETC.

DENSITY AND SPECIFIC GRAVITY.

Density is the weight *in vacuo* of unit volume. On the C.G.S. system it is expressed in grammes per cubic centimetre.

The *Specific Gravity* of a substance is the ratio of its density to that of water at 4° C. (this being the temperature at which water has its maximum density).

The density of water at 4° C. (39°.2 F.) is very little less than unity. According to the latest determination, the weight *in vacuo* of a cubic centimetre of water at 4° C. is 0.999974 gramme (see page 4).

For practical purposes, therefore, 'specific gravity,' as above defined, is identical with 'density.'

The first table (p. 90) gives the weight in pounds per cubic foot and the number of cubic feet per ton corresponding to a given density. The density of a given substance being known, this table gives either its weight per cubic foot or its volume per ton, as may be required. The densities of the principal ores are given on p. 93, those of the rock-forming minerals and gemstones on pp. 94 and 95. The remaining tables give the density and pounds per cubic foot of various mineral substances in common use, of the metals and their alloys and of different kinds of wood.

Table giving the weight in pounds per cubic foot and the number of cubic feet per short ton of 2000 lbs. and per long ton of 2240 lbs. corresponding to a given density.

A density of 1.0=1 gramme per cubic centimetre=62.4278 lbs. per cubic foot.

HARDNESS OF MINERALS.

The hardness of a mineral is measured by the force required to scratch (*i.e.* to separate) the superficial particles of the mineral with a steel point or the sharp-pointed fragment of some harder mineral. In Moh's scale, the hardness of 10 minerals is taken to represent 10 successive degrees of hardness. The degrees of hardness are, however, arbitrarily fixed, and there is no constant ratio between them:

Moh's Scale of hardness.

1. Talc.
2. Gypsum or rock salt.
3. Calcite.
4. Fluorspar.
5. Apatite.
6. Felspar (orthoclase).
7. Quartz.
8. Topaz.
9. Corundum (sapphire).
10. Diamond.

Each of the minerals forming this scale can be scratched by those which follow, and will itself scratch those that precede it in the list; consequently the hardness of a mineral is estimated by its capability of scratching or being scratched by any mineral in this list:

Hardness of gem-stones (on Moh's scale).

Agate,	7	Opal,	7
Beryl (aquamarine, emerald),	7½	Phenakite,	8
Chrysoberyl (Alexandrite),	8½	Quartz (rock-crystal, cairngorm, prase),	7
Corundum (ruby, sapphire),	9	Serpentine,	3
Diamond,	10	Spinel (balas-ruby),	8
Diopside,	5½	Topaz,	8
Felspar (moonstone),	6	Tourmaline,	7
Fluorspar,	4	Turquoise,	6
Garnet (almandine, carbuncle, pyrope, etc.),	7	Zircon (jargoon, hyacinth),	7½
Olivine (peridote, chrysolite),	7

SECTION II. ORE-TONNAGE PER UNIT AREA.

By means of the table on p. 97 the number of tons of an ore or mineral contained in an acre of surface can be calculated if we know the density of the ore or mineral and the average thickness and dip of the vein or bed in which it occurs: for the tonnage given in the table for the angle of dip × the thickness of the vein or bed in feet × the density of the ore or mineral = the number of tons per acre of surface. For example, supposing it is required to know the number of long tons of coal contained in an area of 300 acres, the seam being of an average thickness of 5 feet, having a dip of 6°, and the density of the coal having been determined to be 1.4. For a dip of 6° the table gives the constant 1220.6. Therefore the required tonnage is: $1220.6 \times 5 \times 1.4 \times 300 = 2{,}563{,}260$ long tons. From this figure a considerable deduction has to be made in order to obtain the amount of marketable coal, the percentage to be deducted depending on the local conditions.

The table on p. 98 gives the tons of quartz per Transvaal claim.

* *Smithsonian Geographical Tables*, 1906, p. 170.

† Or Iridio-platinum; 90% platinum and 10% iridium. It is the alloy of which the International Prototype Metric Standards are made.

Table giving the number of short tons (2000 lbs.) and of long tons (2240 lbs.) per acre of surface contained in a vein or bed one foot thick and of a density = 1, for each degree of dip from 0° to 85°.*

Degrees of dip.	Short tons of 2000 lbs. per acre for a density = 1.	Long tons of 2240 lbs. per acre for a density = 1.	Degrees of dip.	Short tons of 2000 lbs. per acre for a density = 1.	Long tons of 2240 lbs. per acre for a density = 1.

SECTION III. UNDERGROUND TEMPERATURES.

The rise in temperature with increasing depth is a factor of great importance in deep-level mining. The rate of increase of temperature in boreholes and deep shafts has therefore to be carefully determined. The method of observing the temperature in deep boreholes by the use of clinical thermometers is described in detail by H. F. Marriott (*Trans. Inst. Min. Met.*, vol. xv., p. 405). Since in deep boring there is a considerable deviation from the vertical, the correct depth at the point of observation can only be obtained by a survey. Several instruments for this purpose have been invented. The simplest and most practical is that invented by Mr. Oehmen of Johannesburg, Transvaal. By this ingenious instrument the deviation from the vertical and the direction of the deviation are recorded by taking photographs of the position of a plumb-bob and a magnetic needle at any desired point in the borehole. The photographs are taken after the instrument has been lowered to the desired point, by means of two small incandescent lamps, which are illuminated by a dry battery by means of a time-contact regulated by a watch. The amount of deviation and its direction are calculated from the photograph after the sensitised paper has been developed at the surface. The amount of deviation is calculated by measuring the distance between the centre of the photograph of the plumb-bob and the centre of the disc, the length of the plumb-bob being a known factor. The direction of the deviation is obtained from the photograph of the magnetic needle, the correct orientation being fixed by two pin-pricks, which have the same relative position both in the photograph of the needle and in that of the plumb-bob.*

* *Brit. Assoc. Rep.* for 1905, p. 404.

Ashton Moss (near Manchester), -	84	2,880	82	1881
Tamerack (Lake Superior), - -	84	4,450	100	1901

From a number of observations made in deep boreholes and mines in the Witwatersrand, Transvaal, Mr. Marriott has deduced a mean rate of increase of temperature for that district of 1° Fahrenheit for each 208 feet of depth, or .48° Fahr. increase per 100 feet of depth. He finds the mean temperature at 1000 feet depth to be 68.75° Fahr. (*Trans. Inst. Min. and Met.*, vol. xv., 1905-6.)

SECTION IV. DATA RELATING TO GOLD AND COPPER RETURNS.

The Valuation of Gold Bullion.

The value of pure gold (1000 fine) is £4 4s. 11.4545d. per troy ounce.* The following table for the valuation of gold bullion is calculated on this basis, namely one troy ounce of gold (1000 fine) equals £4.24773.

Weight in Grains.	Value in pounds sterling.	Weight in Dwts.	Value in pounds sterling.	Weight in Oz. Troy.	Value in pounds sterling.
1	0.00885	1	0.21239	1	4.24773

SECTION V. MINING AREAS OF DIFFERENT COUNTRIES.

AFRICA.

Transvaal.—The unit area for mining on proclaimed ground in the Transvaal is the *Claim.*

For vein and reef mining, the claim has an area of 60,000 square Cape feet. Where practicable it is rectangular in form, measuring 150 Cape feet along the strike by 400 Cape feet in a direction at right angles to the strike.

For alluvial gold mining the claim has an area of 22,500 square Cape feet. Where practicable it is square in form, measuring 150 by 150 Cape feet.

For diamond ('pipe') mining the claim has an area of 900 square Cape feet. Where practicable it is a square of 30 by 30 Cape feet.

For alluvial diamond mining the claim has an area of 1800 square Cape feet. Where practicable it is a rectangle measuring 60 by 30 Cape feet.

A vein or reef claim	=64025.34 sq. British feet	log=4.8063519
	=1.4698195592 acres	log=0.1672640
	=0.694 morgen.	log=9.8416375
1 acre	=0.6803556217 reef claim.	log=9.8327360
1 morgen	=1.44 reef claims.	log=0.1583625

1 morgen	=3.84 alluvial gold claims.	log=0.5843312
A diamond ('pipe') claim	=960.3801 sq. British feet	log=2.9824432
	=0.0220472934 acres	log=8.3433553
	=0.010416 morgen.	log=8.0177288
1 acre	=45.35704155 diamond ('pipe') claims.	log=1.6566447
1 morgen	=96 diamond ('pipe') claims.	log=1.9822712
An alluvial diamond claim	=1920.7602 sq. British feet	log=3.2834732
	=0.044094587 acre	log=8.6443853
	=0.02083 morgen.	log=8.3187588
1 acre	=22.6785208 alluvial diamond claims.	log=1.3556147
1 morgen	=48 alluvial diamond claims.	log=1.6812412

Orange River Colony.—For precious metal mining a reef claim on a public diggings has an area of 60,000 square Cape feet, and where practicable is rectangular in form, measuring 150 Cape feet along the strike by 400 Cape feet in a direction at right angles to the strike. An alluvial gold claim measures 150 by 150 Cape feet, and is either square or as nearly as possible the equivalent thereof.* A diamond ('pipe') claim is 30 by 30, and an alluvial diamond claim 90 by 90 Cape feet.† Concessions for the mining of base metals (including coal, oil, salt, etc.) can be granted by the Government or the private owner as the case may be.

An alluvial diamond claim	= 8643.4209 sq. British feet	log = 3.9366857
	= 0.19842564 acre	log = 9.2975978
	= 0.09375 morgen.	log = 8.9719713
1 acre	= 5.03967128 alluvial diamond claims.	log = 0.7024022
1 morgen	= 10.6 alluvial diamond claims.	log = 1.0280287

For equivalents of reef, alluvial gold and diamond ('pipe') claims, see under Transvaal.

Cape Colony and British Bechuanaland.—A claim on a reef digging is a rectangle measuring 150 Cape feet in the direction of the strike by 800 Cape feet either across or on one side of the reef. On any Government land not proclaimed as a public diggings or on any abandoned public diggings a mining lease of an area not exceeding 100 morgen (211.654 acres) may be granted by the Governor. An alluvial gold claim is a square of 150 by 150 Cape feet. A diamond ('pipe') claim is usually 30 Cape feet square, and an alluvial diamond claim is usually 60 by 30 Cape feet, but the size of the claim to be pegged is stated by the Government on the proclamation of a diamond diggings. Mining concessions for coal, copper or any mineral except gold, silver and platinum are granted by the Government or the private owner, as the case may be.‡

A reef claim	= 128050.68 square British feet	log = 5.1073819
	= 2.939639118 acres	log = 0.4682940
	= 1.38 morgen.	log = 0.1426675
1 acre	= 0.34017781 1 reef claim.	log = 9.5317060
1 morgen	= 0.72 reef claim.	log = 9.8573325

For equivalents of alluvial gold, 'pipe' and alluvial diamond claims, see under Transvaal.

* The O.R.C. Precious Metals Ordinance of 1904.

† The O.R.C. Precious Stones Ordinance of 1904.

‡ Cape of Good Hope Colony, Precious Minerals Act of 1898 and Precious Stones Act of 1899.

Natal.—The claim for the mining of gold and other minerals, including coal, but excepting precious stones and alluvial minerals, must not exceed 300 by 300 yards (18.595 acres). A mineral claim for the mining of coal, limestone, stratified ironstone, slate, soapstone, and such minerals as may from time to time be included by order of the Governor in Council, must not exceed 700 by 700 yards (101.239 acres).* An alluvial claim for the mining of alluvial deposits of precious stones or minerals must not exceed 100 by 100 British feet (0.229 acre).

Rhodesia.—A reef claim is a rectangle of 150 by 600 Cape feet, the shorter sides of which are parallel to the strike of the reef. It carries the so-called 'extra-lateral right,' that is, the reef can be followed underground beyond the vertical planes in which the surface boundaries lie. Reef claims are pegged in blocks of 10, a block being under ordinary circumstances a parallelogram of 1500 by 600 Cape feet, and in no case of a greater area than 900,000 square Cape feet. An alluvial gold claim must, where possible, be a square of 200 by 200 Cape feet, and must in no case contain more than 40,000 square Cape feet. Coal mining locations of either 50, 100 or 150 morgen (105.827, 211.654 or 327.481 acres) are granted. A copper-mining location may be pegged of an area equivalent to not more than 30 reef claims of 90,000 square Cape feet each. No extra lateral rights exist in the mining of coal or copper locations.†

A reef claim	=96038.01 sq. British feet	log=4.9824432
	=2.20472934 acres	log=0.3433553
	=1.0416 morgen.	log=0.0177288
1 acre	=0.453570415 5 reef claim.	log=9.6566447
1 morgen	=0.96 reef claim.	log=9.9822712
A block of 10 reef claims	=22.0472934 acres	log=1.3433553
	=10.416 morgen.	log=1.0177288
An alluvial gold claim	=42683.56 sq. British feet	log=4.6302606
	=0.9798797 acre	log=9.9911727
	=0.4629 morgen.	log=9.6655462
1 acre	=1.02053343 alluvial gold claims.	log=0.0088273
1 morgen	=2.16 alluvial gold claims.	log=0.3344538

* Natal Mines Act of 1899.

† The British South Africa Company's Mining Ordinance of 1903.

The Gold Coast Colony and Ashanti.—Mining concessions obtained from natives must not exceed five square miles in area. This does not apply to concessions obtained and registered previous to October 1895.*

Egypt.—There is no definite limit as to the size of a mining lease, which may be granted by the Government at a price per *feddan* (.420083 hectare or 1.038086 acres), which varies according to the nature of the mineral to be mined. There is in addition a tax of 10% on all net profits accruing from the working of the lease.

Sudan.—The maximum areas of mining leases are:

For non-alluvial gold,	64	hectares	or 160	acres.
„ silver,	64	„	„ 160	„
„ any other metal,	128	„	„ 320	„
„ oil,	256	„	„ 640	„
„ coal,	512	„	„ 1280	„

Each lease must be rectangular in shape, and of a length not exceeding four times its breadth.†

AUSTRALASIA.

New South Wales.—A gold-mining lease must not exceed an area of 25 acres, except when the Secretary for Mines is "satisfied that special difficulties exist in working the ground either by way of great depth or wetness, or on account of the cost by appliances required." In such case a special lease is granted, the tenure, form and area of which is prescribed by the Governor. If an ordinary gold-mining lease not exceeding 25 acres be located on a quartz vein or lode, the maximum length (measured in the direction of the strike) is 600 yards and the maximum width (measured across the lode) 200 yards. "In no case shall the area be marked out so that the lode will be distant from either extremity of the boundaries defining the width of the said area less than one-tenth of such width, nor shall the length along the lode in any such area be

* The Gold Coast Colony and Ashanti Concessions Ordinance of 1900.

† *Mining Laws of the British Empire*, C. J. Alford, London, 1906, p. 35 *et seq.*

greater than three times the width of such area."* All other gold-mining leases must be, where practicable, in the form of a parallelogram, the maximum length of which must not be more than twice the maximum breadth. "The area of a mining lease for any mineral shall not exceed 640 acres and (unless specially authorised by the Secretary for Mines) shall not be less than 40 acres for coal-mining lots, and shall not exceed 80 acres nor be less than 20 acres for other mineral lots." . . . "Mineral lots shall be measured in the form of a square, except in any case where the Minister shall authorise a departure from that form."†

Queensland.—The area of a gold-mining lease is limited to 12 acres until seven years from the date of the proclamation of the gold-field, or to 25 acres until fourteen years from the date of proclamation. After the expiration of this latter period the area of the lease may be extended to 50 acres if the ground in question has previously been worked and abandoned, or if, in the opinion of the Warden of the gold-field, the undue wetness or great depth of the workings and the consequent high working costs warrant the extension. A mining lease for silver, antimony or tin within the limits of any gold-field or mineral-field specially notified by proclamation shall not exceed 80 acres, and beyond such limits shall not exceed 120 acres. The maximum area of a mining lease for any other mineral except coal is 160 acres. A coal-mining lease may not be larger than 320 acres, except in the case of the discovery of a new seam of coal at least 15 miles from any known payable coal-field, or of a hitherto unknown coal seam at a depth of at least 600 feet. The discoverer in such case is entitled to a lease of 640 acres.‡ Wherever practicable, a mining lease must be rectangular in form, with the length not exceeding twice the breadth, but in special cases leases of irregularly shaped areas may be granted.

South Australia.—The maximum areas of mining leases are: for gold, 20 acres; for other minerals except coal, oil, salt and gypsum, 40 acres; for coal, oil, salt or gypsum, 640 acres.

* The New South Wales Mining Act of 1874, Section 36.

† *Regulations relating to Mineral Leases on Crown Lands*, February 1885.

‡ The Mining Act of Queensland, 1898.

Any number of leases may be held by one person, but not more than four adjoining gold or mineral leases may be amalgamated.*

Victoria.—The maximum area of a gold-mining lease is 100 acres, while a mining lease for any other mineral (including coal) must not exceed 640 acres. There are no regulations as to the form of a mining lease.†

West Australia.—The maximum area of an ordinary gold-mining lease is 24 acres; but where the ground has previously been worked for alluvial gold and afterwards abandoned, or where, in the opinion of the Warden, the working will be costly by reason of excessive wetness or great depth, a lease not exceeding 48 acres may be granted. The maximum area of a mining lease for all minerals, except gold and coal, is 48 acres. A coal-mining lease must not exceed 320 acres, except in the case of the discovery of a new seam of coal at least 15 miles from any known payable coal. The discoverer in such case is granted a lease of 640 acres free of royalty for ten years.‡

Tasmania.—The maximum area of a gold-mining lease is 20 acres. A mining lease for coal, shale, slate, freestone or limestone must not exceed 320 acres, while the maximum area of a mining lease for any mineral except those already mentioned is 80 acres. If gold be found associated or combined with other minerals in such proportion that the amount recovered is of less value than that of the minerals with which it is associated or combined, the lease may have a maximum area of 80 acres. All mining leases must, where practicable, be square in form with the bearings of the boundary lines corresponding to the cardinal points of the compass. Two or more leases may be amalgamated.§

New Zealand.—The unit of mining area in New Zealand is the *Claim*. Claims may be either *ordinary*, *extended* or *special*. The maximum areas are: for an ordinary claim, 1 acre if under license, or 10,000 square feet if not under license; for an extended claim, 5 acres; and for a special claim, 100 acres.

* From the South Australian Mining Act of 1893.
† The Victorian Mines Acts of 1890 and 1897.
‡ The Mining Act of West Australia, 1904.
§ Tasmanian Mining Acts of 1900 and 1905.

The maximum lengths in the direction of the strike of the reef are: for an ordinary *quartz* claim 200 feet, and for an extended quartz claim 500 feet. The maximum lengths along the watercourse are: for an ordinary *dredging* or river claim, 3 chains (198 feet); for an extended dredging claim, 15 chains (990 feet): and for a special dredging claim, 1 mile. The maximum lengths of shore frontage are: for an ordinary *sea-beach* claim, 200 feet; for an extended sea-beach claim, 500 feet; and for a special sea-beach claim, 1 mile. A special sea-beach claim may be extended beyond 100 acres * in the seawards direction.

NORTH AMERICA.

British Columbia.—From 1884 to 1892 the vein-mining claim of British Columbia was the same as that of the United States, namely, an area of 1500 by 600 feet, carrying the 'extra-lateral right.' The Mineral Act, however, was revised in 1891, and further augmented in 1896 and 1897. It now defines the unit of mining area as a rectangular claim not exceeding 1500 feet in either length or width (measured horizontally), with no extra-lateral right. The underground rights are therefore confined to the vertical planes in which the surface boundaries lie.

A vein-mining claim	= 51.65289 acres	log = 1.7130946
	= 20.90315 hectares.	log = 1.3202116
1 acre	= .01936 claim.	log = 8.2869054
1 hectare	= .0478397 claim.	log = 8.6797884

In 'creek diggings' a placer claim is 250 feet square, the side lines of which must run in the general direction of the watercourse or stream. In 'bar diggings' a placer claim may be either 250 feet square on any bar which is covered at high water, or 250 in length, and of the width contained between the high-water and the extreme low-water marks. In 'dry diggings' a claim is 250 feet square.

A placer claim must be as nearly as possible rectangular in form. The maximum length of a dredging lease is 5 miles. The maximum areas of leases for hydraulicing and precious stone diggings are 80 acres and 10 acres respectively. A coal or petroleum lease is a square block of a maximum area of 640 acres.

* New Zealand Mining Act, No. 38 of 1898.

Nova Scotia.—For gold and silver mining the unit area is a rectangle measuring 250 feet by 150 feet, laid off with the shorter sides running east and west. Any number of these areas, not exceeding 100, can be taken up. For the mining of other minerals an area of 5 square miles, not exceeding $2\frac{1}{2}$ miles in length, may be granted.

Quebec.—The total area of the mining concessions which can be acquired by one person is 400 acres, but under special circumstances the Lieutenant-Governor in Council may grant an area not exceeding 1000 acres.

Ontario.—A mining claim may be either 15 chains square ($22\frac{1}{2}$ acres) or 20 chains square (40 acres).

New Brunswick.—From 10 to 100 rectangular areas of 250 by 150 feet may be acquired for gold and silver mining. The boundaries must be laid off in the direction of the cardinal points of the compass. Mining leases of a maximum area of one square mile are granted for oil, natural gas or any mineral excepting gold and silver, but the Surveyor-General may, under special circumstances, sanction a larger lease.

Manitoba and the North-West Territories.—A gold quartz claim is a square of 1500 by 1500 feet without the extra-lateral right (see British Columbia).

Placer mining claims generally are 100 feet square. On the North Saskatchewan River, placer claims "are either bar or bench, the former being 100 feet long and extending between high and low-water mark. The latter includes bar diggings, but extends back to the base of the hill or bank, but not exceeding 1000 feet. Where steam power is used, claims 200 feet wide may be obtained."

Two dredging leases of five miles each may be obtained. "The lessee's right is confined to the submerged bed or bars of the river below low-water mark, and subject to the rights of all persons who have, or who may receive entries for bar diggings or bench claims, except on the Saskatchewan River, where the lessee may dredge to high-water mark on each alternate leasehold."

For iron and mica the maximum area of a location is 160 acres; a coal-mining location may not exceed 320 acres; and the

(2 hectares or 4.942116 acres). The maximum holding is limited to 240 hectares (593.05395 acres, 60 large or 120 small pertenencias). There is no 'extra-lateral right.'

ASIA.

British India.—The Collector of any district in British India can grant a prospecting license carrying with it the right to a lease for 30 years on a block of ground of any size not exceeding 1 square mile, provided the ratio of the length (in the direction of strike of the vein) to the breadth does not exceed 4 to 1. Applications for more than 1 square mile are dealt with by the Board of Revenue.

In the Native State of Mysore, the size of the mining area granted to one applicant is limited to 2 square miles.

Ceylon.—On Crown lands, mining leases for one or more blocks, each of which must be over 10 and not more than 100 acres in extent, may be granted by the Governor, but the total area held by the lessee or by those joined in interest with him must not exceed 500 acres. Except when specially sanctioned, the length of a block must not exceed four times its breadth.*

Malay Peninsula.—Mining leases for large areas are granted by the Sultan of Pahang on the recommendation of the British Resident; but mining permits giving the holder the right to dig for gold and tin within an area of 5 acres are also granted.†

Russian Empire.—For vein-mining the maximum area of an *Otwod* or concession is 1 square verst (1.138062 square kilometres or .439408 square mile). The ratio of the length (in the direction of the strike of the vein) to the breadth must not exceed 3 to 1.

For alluvial mining in Siberia, the length of the concession is limited to 5 versts (5.3340 kilometres or 3.314394 miles), while the breadth may extend to the full width of the valley in which the auriferous gravels lie. In the Urals the size of

* From *Mining Laws of the British Empire*, by C. J. Alford, London, 1906, p. 64.

† The States of Pahang Mining Enactment of 1904.

horizontal projection gives a square, each side of which measures 100 metres; and bounded underground by the four vertical planes corresponding to the sides of the said square."

1 pertenencia	= 1 hectare	
	= 2.471058 acres.	log = 0.3928830
1 acre	= 0.404685 pertenencia.	log = 9.6071170

SOUTH AMERICA.

British Guiana.—A gold-mining claim must not exceed 1500 feet in length by 800 feet in width. A claim located for the purpose of searching for precious stones must not exceed 1500 feet in length by 800 feet in width, nor contain a greater area than 500 acres. A claim must, where practicable, be rectangular in form and it is limited underground by the vertical planes in which the surface boundaries lie.*

Colombia.—The unit area for vein mining is 600 by 240 metres, and for alluvial mining 5 by 2 kilometres.†

1 vein-mining area	= 14.4 hectares	log = 1.1583625
	= 35.583235 acres.	log = 1.5512455
1 hectare	= .0694 vein-mining claim.	log = 8.8416375
1 acre	= .028103 vein-mining claim.	log = 8.4487545
1 alluvial-mining area	= 10 sq. kilometres	
	= 1000 hectares	
	= 2471.05814 acres	log = 3.3928830
	= 3.86103 square miles.	log = 0.5867030

Chile.—For coal the mining area or pertenencia is 50 hectares (123.5529 acres); while for any other mineral it may be from 1 to 5 hectares (2.47106 to 12.3553 acres). There is no 'extra-lateral right.' ‡

Peru.—The mining area or pertenencia for gold, silver, platinum, lead, tin, copper, antimony, zinc, coal or petroleum is a square of 200 by 200 metres (4 hectares or 9.88423 acres), while a pertenencia located on a deposit of borax, sulphur or any other non-metallic mineral is half that size

* British Guiana Mining Regulations, 1903.

PART VI. DATA RELATING TO SURVEYING.

SECTION I. TRIGONOMETRICAL AND MISCELLANEOUS FORMULÆ AND CONSTANTS.

LET A be any acute angle, and let a perpendicular BC be drawn from any point in one side to the other side. Then, if the sides

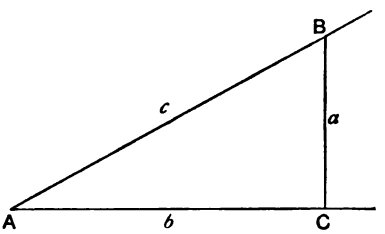

FIG. 1.

of the right triangle thus formed are denoted by letters, as in the figure, we have these six formulæ:

1. $\sin A = \frac{a}{c}$.
2. $\cos A = \frac{b}{c}$.
3. $\tan A = \frac{a}{b}$.
4. $\operatorname{cosec} A = \frac{c}{a}$.
5. $\sec A = \frac{c}{b}$.
6. $\cot A = \frac{b}{a}$.

Solution of Right Angles. (Fig. 1.)

	GIVEN.	SOUGHT.	FORMULÆ.
7.	a, c	A, B, b	$\sin A = \frac{a}{c}$, $\cos B = \frac{a}{c}$, $b = \sqrt{(c+a)(c-a)}$.
8.	a, b	A, B, c	$\tan A = \frac{a}{b}$, $\cot B = \frac{a}{b}$, $c = \sqrt{a^2+b^2}$.
9.	A, a	B, b, c	$B = 90° - A$, $b = a \cot A$, $c = \frac{a}{\sin A}$.
10.	A, b	B, a, c	$B = 90° - A$, $a = b \tan A$, $c = \frac{b}{\text{c s } A}$.
11.	A, c	B, a, b	$B = 90° - A$, $a = c \sin A$, $b = c \cos A$.

Solution of Oblique Triangles. (Fig. 2.)

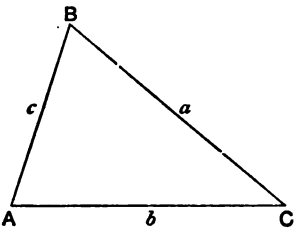

FIG. 2.

	GIVEN.	SOUGHT.	FORMULÆ.
12.	A, B, a	b	$b=\frac{a\sin B}{\sin A}=a\sin B\operatorname{cosec} A.$
13.	A, a, b	B	$\sin B=\frac{b\sin A}{a}.$
14.	a, b, C	A, B	$\tan\frac{1}{2}(A-B)=\frac{a-b}{a+b}\cot\frac{1}{2}C,$ then $A=(90^\circ-\frac{1}{2}C)+\frac{1}{2}(A-B)$ and $B=(90^\circ-\frac{1}{2}C)-\frac{1}{2}(A-B),$ a being the longer side.
15.	a, b, c	A	Let $s=\frac{1}{2}(a+b+c)$: $\sin\frac{1}{2}A=\sqrt{\frac{(s-b)(s-c)}{bc}}$; $\cos\frac{1}{2}A=\sqrt{\frac{s(s-a)}{bc}}$, $\tan\frac{1}{2}A=\sqrt{\frac{(s-b)(s-c)}{s(s-a)}}$; $\sin A=\frac{2\sqrt{[s(s-a)(s-b)(s-c)]}}{bc}.$
16.	A, B, C, a	Area	$\text{Area}=\frac{a^2\sin B\sin C}{2\sin A}.$
17.	A, b, c	Area	$\text{Area}=\frac{1}{2}bc\sin A.$
18.	a, b, c	Area	Let $s=\frac{1}{2}(a+b+c)$: $\text{area}=\sqrt{s(s-a)(s-b)(s-c)}.$

Astronomical Constants (Harkness).

Sidereal year = 365.2563578 mean solar days.

Sidereal day = 23 hours 56 min. 4.100 seconds mean solar time.

Mean solar day = 24 hours 3 min. 56.546 seconds sidereal time.

Mean distance of the earth from the sun = 92,800,000 miles.

Geodetic Constants.

Dimensions of the earth (Clarke's spheroid):

Equatorial semi-axis 3963.3 miles.

Polar „ 3949.8 „

Perimeter of meridian ellipse 24,854.76 miles.

Circumference of equator 24,901.96 „

Area of earth's surface 196,940,400 sq. miles.

Mean density of the earth (Harkness) 5.576 ± 0.016.

Surface density of the earth (Harkness) 2.56 ± 0.16.

Acceleration of gravity at sea-level (Harkness)

$= 980.60\ (1 - 0.002662 \cos 2\phi)$ centimetres per second,

where ϕ = the latitude.

Length of seconds pendulum (Harkness)

$= 0.990910 + 0.005290 \sin^2\phi$ metres,

where ϕ = the latitude.

SECTION II. THE COORDINATION OF SURVEY POINTS.

The permanent stations of a modern survey are usually plotted by means of rectangular coordinates, the use of the protractor being restricted to the draughting of the temporary points and

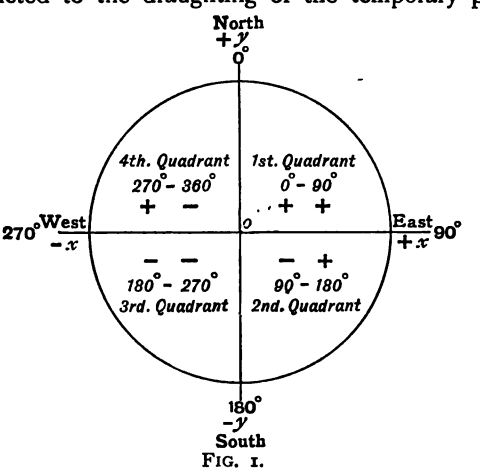

FIG. 1.

detail. The customary method of coordinating a survey is as follows:

The most prominent and central station of the survey, from which the direction of the true meridian has been determined, is selected as the 'point of origin' *o*. At this point two fixed *axes*, y and x, are assumed to intersect at right angles, the direction of the y axis being made to coincide with the true meridian. From the starting point *o*, the *latitude* (distance north or south) and the *departure* (distance east or west) of each station of the survey are calculated, the latitudes being the y and the departures the x coordinates.

The y coordinates to the north of, and the x coordinates to the east of o are positive and carry a plus sign, while those to the south of and to the west of o are negative and carry a minus sign. They are stated with the ys before (to the left of) the xs; thus $+950.13 - 726.48$ may represent the coordinates of a point 950.13 units north of, and 726.48 units west of o. From o, the bearing of the true north (along the y axis) is taken as 360° or 0°, the east (along the x axis) as 90°, the south as 180° and the west as 270°. Therefore, if the coordinates of a point carry the signs:

+	+,	its bearing from o is	in the	1st	quadrant	between	0°	and	90°
−	+,	„	„	2nd	„	„	90°	„	180°
−	−,	„	„	3rd	„	„	180°	„	270°
+	−,	„	„	4th	„	„	270°	„	360°

Coordinates are usually calculated by means of logarithms and checked by natural sines and cosines, using 'short' multiplication.*

EXAMPLE. Given the measured lengths

$$oA = 377.92,\ AB = 1015.74 \text{ and } BC = 284.63,$$

and the observed angles $yoA = 47° 19' 20''$ (the bearing of the line oA), $oAB = 83° 47' 40''$ and $ABC = 321° 33' 50''$. The coordinates of the points A, B and C are calculated as follows:

To Determine A.

	(By logarithms.)		*Check.* (By nat. sines and cosines.)	
Length $oA = 377.92$	$= 2.5773999$	$= 2.5773999$	37792	37792
Bearing $oA = 47° 19' 20''$	$\cos = 9.8311493$	$\sin = 9.8663922$	78776	81537
	2.4085492	2.4437921	22675	26454
			2645	1134
	$+256.18$	$+277.84$	265	189
	$o = \pm\ 0.00$	$\pm\ 0.00$	33	7
	$A = +256.18$	$+277.84$	$+256.18$	$+277.84$

* Rule for 'short' multiplication: Reverse the multiplier and place it below the multiplicand so that its unit figure (the one preceding the decimal point) is directly under that decimal place of the multiplicand to which the product is required. For example, to multiply 103.75 by 39.445, the product being required to two decimal places, the unit figure 9 is placed under the 5.

Therefore in checking by natural sines and cosines, in order to get the product to two decimal places reverse the function and place its initial figure under the first decimal place of the multiplicand. (See the above calculation, where .67787 = the nat. cos of 47° 19' 20'').

	$B = +924.13$	-487.39	$+924.13$	-487.39

To Determine *C*.

			Check.	
Length $BC = 284.63$	$= 2.4542807$	$= 2.4542807$	28463	28463
Bearing $BA = 131° 7' 00''$			77640	19899
Angle $ABC = 321° 33' 50''$				
Bearing $BC = 92° 40' 50''$	sin $= 8.6699437$	cos $= 9.9995245$	1138	25617
	1.1242244	2.4538052	171	2562
			20	228
	-13.31	$+284.32$	2	25
	$B = +924.13$	-487.39	-13.31	$+284.32$
	$C = +910.82$	-203.07	$+910.82$	-203.07

The bearing of a line = that of the backsight + its angle with reference to the backsight (measured clockwise, from left to right); and the bearing of the line used as a backsight differs by 180° from its bearing when a foresight. For example, in the above calculations the bearing of the line *oA* is 47° 19′ 20″; therefore, when used as a backsight from the station *A*, its bearing is 47° 19′ 20″ + 180° = 227° 19′ 20″, which, added to the observed angle *oAB* which *Ao* makes with *AB*, gives the bearing of the line *AB*.

Similarly the bearing *BC* = (the bearing *AB* − 180°) + the angle *ABC*, which sum, being greater than 360°, has that amount deducted from it. A bearing is denoted by the prefix *y*. For example, *yAB* signifies the bearing of the line *AB*, or its direction with reference to *y* (the true north, 0°).

If the bearing of a line be in the 1st quadrant,

its length × the cosine of the bearing is the *y* distance or latitude,
" × the sine " " *x* " departure;

if in the 2nd quadrant,

its length × the sine of the (bearing − 90°) is the *y* distance or lat.,
" × the cosine " " *x* " departure;

if in the 3rd quadrant.

its length × the cosine of the (bearing − 180°) is the y distance or lat.,
„ × the sine „ „ „ x „ departure;

and if in the 4th quadrant,

its length × the sine of the (bearing − 270°) is the y distance or lat.,
„ × the cosine „ „ „ x „ departure.

To coordinate any point B which has been fixed from a coordinated point A, the y and the x distances of B from A are added algebraically to the coordinates of A. For example, in the foregoing calculations the y distance $AB = +667.95$, and the x distance $AB = -765.23$, which, when added algebraically to the coordinates of A, give the coordinates of B with reference to the point of origin o.

Method used in calculating the length and bearing of a line connecting two coordinated points:

		Check.	
$A = +256.18 + 277.84$		101574	101574
$B = +924.13 - 487.39$		495756	73357
Diff. $= +667.95 - 765.23$		60944	71102
		5079	5079
		711	305
		61	37
		$+667.95$	-765.23
$667.95 = 2.8247440$			
$765.23 = 2.8837920$			
$9.9409320 = \tan$	$41° 7' 00''$		
	$270° 0' 00''$		
cosine $41° 7' 00'' = 9.8770096$	$311° 7' 00'' = vAB.$		
(Subtracted from log 765.23) $3.0067824 =$	$1015.74 =$ length $AB.$		

The signs before the y and x differences of the coordinates of the two points indicate the quadrant in which the bearing of the connecting line lies. Divide the y difference by the x difference. Then:

$$\frac{y \text{ difference}}{x \text{ difference}} = \begin{cases} \text{the cotangent of the bearing} & \text{if in the 1st quadrant.} \\ \text{the tangent of (the bearing} - 90°) & \text{„ 2nd „} \\ \text{the cotangent of („} - 180°) & \text{„ 3rd „} \\ \text{the tangent of („} - 270°) & \text{„ 4th „} \end{cases}$$

For example, in the foregoing calculation, as the differences carry the signs + −, the bearing is in the 4th quadrant. Consequently $\frac{667.95}{765.23}$ = the tangent of $41° 7' 00''$, which, $+ 270°$, $= 311° 7' 00'' = yAB.$

The distance between the two points =

$$\frac{y \text{ difference}}{\text{cosine of the bearing}} \quad \text{or} \quad \frac{x \text{ difference}}{\text{sine of the bearing}}$$

if the bearing be in the 1st quadrant.

$$\frac{y \text{ difference}}{\text{the sine of (the bearing} - 90^\circ)} \quad \text{or} \quad \frac{x \text{ difference}}{\text{cosine of (the bearing} - 90^\circ)}$$

if the bearing be in the 2nd quadrant.

$$\frac{y \text{ difference}}{\text{cosine of (the bearing} - 180^\circ)} \quad \text{or} \quad \frac{x \text{ difference}}{\text{sine of (the bearing} - 180^\circ)}$$

if the bearing be in the 3rd quadrant.

$$\frac{y \text{ difference}}{\text{sine of (the bearing} - 270^\circ)} \quad \text{or} \quad \frac{x \text{ difference}}{\text{cosine of (the bearing} - 270^\circ)}$$

if the bearing be in the 4th quadrant.

For example, in the foregoing calculation the bearing is in the 4th quadrant. Consequently $\frac{765.23}{\text{cosine } 41^\circ\ 7'\ 00''} = 1015.74$, the length of the line AB.

Method used in calculating the coordinates of a triangulation.

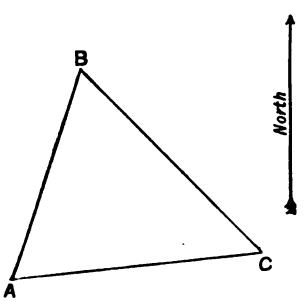

FIG. 2.

Given the coordinates of the points A and C, and by observation the interior angles of the triangle ABC. Required the coordinates of the point B.

Angles.	Coordinates.	
	y	x
$A = 72^\circ\ 15'\ 30''$	$A = +7230.91$	$+\ 538.64$
$B = 51^\circ\ 55'\ 40''$		
$C = 55^\circ\ 48'\ 50''$	$C = +8522.77$	$+9367.05$

The first step is to determine the length and bearing of the line AC:

		Check.	
$A = +7230.91 + 538.64$		892243	892243
$C = +8522.77 + 9367.05$		887441	364989
$+1291.86 + 8828.41$		89224	803019
3.1112155		35690	71379
3.9458825		3569	8030
9.1653330 = 81° 40′ 30″ = yAC		625	357
9.9953994		78	56
3.9504831 = 8922.43 = AC.		+1291.86	+8828.41

The coordinates of B are then determined from the two sides AB and CB, each calculation acting as a check on the other. The lengths of these sides are:

$AB = AC$ sine C cosecant B, and $BC = AC$ sine A cosecant B; and their bearings are derived from the known bearing yAC, and the observed angles of the triangle. The logarithm of the cosecant of B is got by subtracting the logarithm of the sine from 10.0000000. This is most easily done by subtracting each figure from 9, except the right-hand one, which is subtracted from 10.

$yAC = 81° 40′ 30″$			$yCA = 261° 40′ 30″$		
$A = 72° 15′ 30″$			$C = 55° 48′ 50″$		
$yAB = 9° 25′ 00″$			$yCB = 317° 29′ 20″$		
			$B = 51° 55′ 40″$		
log 8922.43 = 3.9504832			(Check) $yAB = 9° 25′ 00″$		
cosec B = 0.1038961					
sin A = 9.9788377					
sin C = 9.9176193					
log AB = 3.9719986	3.9719986		log CB = 4.0332170	4.0332170	
yAB = 9.9941079	9.2138176		yCB = 9.8675537	9.8297752	
3.9661065	3.1858162		3.9007707	3.8629922	
+ 9249.25	+1533.97		+ 7957.39	−7294.44	
A = + 7230.91	+ 538.64		C = + 8522.77	+9367.05	
B = +16480.16	+2072.61		B = +16480.16	+2072.61	

The method of calculating the lengths of the sides AB and CB is not clear in the finished calculation. It is as follows: First, to determine the length AB,

$$\begin{aligned} \log 8922.43 &= 3.9504832 \\ \operatorname{cosec} B &= 0.1038961 \\ \sin A &= \\ \sin C &= 9.9176193 \\ \hline \log AB &= 3.9719986 \end{aligned}$$

the space for the $\log \sin A$ being left blank. Then, to determine the length CB, $\log \sin A$ is filled in, and the sum of the three top lines $= \log CB$, which is placed to the right of the repeated $\log AB$.

Then, as already described, $AB \times$ the cos and sin of yAB (1st quadrant) = the latitude and departure of B from A; and $CB \times$ the sin and cos of $yCB - 270°$ (4th quadrant) = the latitude and departure of B from C.

Calculation of the area of a figure from its coordinates.

$$\text{Area} = \frac{\text{sums of the } y\text{s} \times \text{diffs. of the } x\text{s}}{2} \text{ or } \frac{\text{sums of the } x\text{s} \times \text{diffs. of the } y\text{s}}{2}$$

The sum and difference of the coordinates of each two adjoining points is taken separately, and the sum of the products is divided by 2, care being taken to distinguish between the positive and the negative signs when making the addition. The computation is checked by calculating by each way separately, using either 'short' multiplication or logarithms as preferred, the former method being the more accurate for dealing with large amounts.

For example, in the triangle ABC we have the coordinates:

	y	x
A =	+ 7230.91	+ 538.64
B =	+ 16480.16	+ 2072.61
C =	+ 8522.77	+ 9367.05

	Sums of the ys.		Diffs. of the xs.	
AB	+ 23711.07	×	+ 1533.97	= + 36,372,070.04
BC	+ 25002.93	×	+ 7294.44	= + 182,382,372.71
CA	+ 15753.68	×	− 8828.41	= − 139,079,946.05
				+ 79,674,496.70
				÷ 2 = 39,837,248.35

Check.

	Sums of the xs.		Diffs. of the ys.	
AB	+ 2611.25	×	+9249.25	= +24,152,104.06
BC	+11439.66	×	−7957.39	= −91,029,836.09
CA	+ 9905.69	×	−1291.86	= −12,796,764.68
				−79,674,496.69
				÷2 = 39,837,248.35

Area ABC = 39,837,248.35 square units.

The calculation of an area may often be simplified by deducting either a positive or a negative constant from each of the ys, and similarly, another positive or negative constant from each of the xs.

For example, in the foregoing calculation + 7000y and + 500x may be deducted from the coordinates of A, B and C, giving:

	y	x
A =	+ 230.91	+ 38.64
B =	+9480.16	+1572.61
C =	+1522.77	+8867.05

	Sums of the ys.		Diffs. of the xs.	
AB	+ 9711.07	×	+1533.97	= +14,896,490.05
BC	+11002.93	×	+7294.44	= +80,260,212.71
CA	+ 1753.68	×	−8828.41	= −15,482,206.05
				+79,674,496.71
				÷2 = 39,837,248.35

Check.

	Sums of the xs.		Diffs. of the ys.	
AB	+ 1611.25	×	+9249.25	= +14,902,854.06
BC	+10439.66	×	−7957.39	= −83,072,446.08
CA	+ 8905.69	×	−1291.86	= −11,504,904.68
				−79,674,496.70
				÷2 = 39,837,248.35

Area ABC = 39,837,248.35 square units.

Calculation of the coordinates of a point, the angles which it makes with three coordinated points having been observed.

Given the coordinates of the points A, C and B, and the observed angles ARC and BRC which subtend these points at R. Required the coordinates of the point R (Fig. 3).

Describe a circle cutting A, B and R. Join RA, RB, RC

and AB. Produce RC to the circumference of the circle at D, and join AD and BD. Then:

the observed angle ARD = the angle ABD
and the observed angle BRD = the angle BAD,

as they subtend the same chords AD and BD. Determine the length and bearing of AB and coordinate D from the triangle ABD. Then calculate the bearing yCD which = the bearing yRD. Determine yRA and yRB from yRC and the angles ARD and BRD, and coordinate R from the triangle ABR.

It is apparent that the calculation will not be accurate when the middle point C is close to the circumference of the circle,

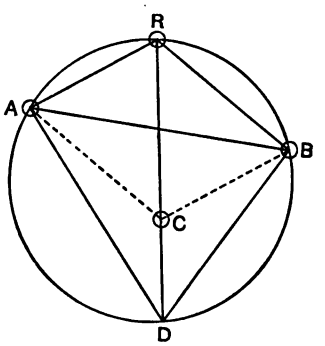

FIG. 3.

and quite impossible when C is cut by the circle. It is therefore advisable to first add the observed angles ARC and BRC to the known angle ACB; if their sum be 180°, all four points will be cut by the circle, as the opposite angles of a quadrilateral inscribed within a circle are together equal to 180°. Therefore, when the sum of the angles ARC, BRC and ACB is more than 180°, C is inside the circle and $yCD = yRD$; and when it is less than 180°, C is outside the circle and $yCD = yDR$.

R may also be calculated by the following formula:

Let $T = (\angle RBC + \angle RAC) = 360° - (\angle ACB + \angle ARC + \angle BRC)$.
When T is 90° or under,

$$\text{cotan } RBC = \text{cotan } T\left(\frac{BC \sin ARC}{AC \sin BRC \cos T} + 1\right).$$

When T is between 90° and 180°, the 1 in the formula is negative instead of positive, thus:

$$\text{cotan } RBC = \text{cotan } T\left(\frac{BC \sin ARC}{AC \sin BRC \cos T} - 1\right).$$

R is then coordinated from the triangle CBR.

The Cape System.

In South Africa, a method of coordination which is known as the *Cape System* is in general use. It differs from the conventional method in that the x axis is positive to the *west*, which is taken as 360° or 0°, and the bearings are therefore stated with reference to the west instead of to the north, the bearing of a line being consequently denoted by the prefix x instead of y. It is best explained by the following diagram:

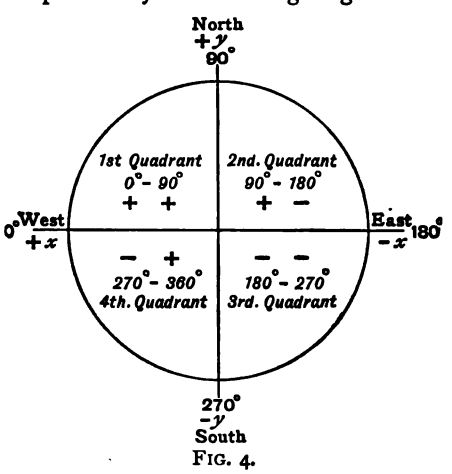

FIG. 4.

The methods of calculation are similar to those already described, but the arrangement of the quadrants is of course quite different. Therefore, if the bearing of a line be:

In the 1st quadrant,	its length	×	the sin of the bearing	is the	y	distance.			
	,,	×	,, cos	,,	,,	,,	x	,,	
,, 2nd ,,	,,	×	,, cos	,,	(bearing − 90°)	is the	y	distance.	
	,,	×	,, sin	,,	(,,	,,)	,, x	,,	
,, 3rd ,,	,,	×	,, sin	,,	(bearing − 180°)	,,	y	,,	
	,,	×	,, cos	,,	(,,	,,)	,, x	,,	
,, 4th ,,	,,	×	,, cos	,,	(bearing − 270°)	,,	y	,,	
	,,	×	,, sin	,,	(,,	,,)	,, x	,,	

In determining the length and bearing of a line between two coordinated points:

$$\frac{y \text{ difference}}{x \text{ difference}} = \begin{cases} \text{the tan of the bearing if in the 1st quadrant.} \\ \text{,, cotan of (the bearing} - 90^\circ\text{) if in the 2nd quadrant.} \\ \text{,, tan ,, (} \quad \text{,,} \quad -180^\circ\text{) ,, 3rd ,,} \\ \text{,, cotan ,, (} \quad \text{,,} \quad -270^\circ\text{) ,, 4th ,,} \end{cases}$$

$$\text{Length} = \frac{y \text{ difference}}{\sin \text{ of bearing}} \text{ or } \frac{x \text{ difference}}{\cos \text{ of bearing}} \text{ if in the 1st quadrant.}$$

$$\text{,,} = \frac{y \text{ difference}}{\cos \text{ of (bearing} - 90^\circ\text{)}} \text{ or } \frac{x \text{ difference}}{\sin \text{ of (bearing} - 90^\circ\text{)}} \text{ ,, 2nd ,,}$$

$$\text{,,} = \frac{y \text{ difference}}{\sin \text{ of (bearing} - 180^\circ\text{)}} \text{ or } \frac{x \text{ difference}}{\cos \text{ of (bearing} - 180^\circ\text{)}} \text{ ,, 3rd ,,}$$

$$\text{,,} = \frac{y \text{ difference}}{\cos \text{ of (bearing} - 270^\circ\text{)}} \text{ or } \frac{x \text{ difference}}{\sin \text{ of (bearing} - 270^\circ\text{)}} \text{ ,, 4th ,,}$$

SECTION III. THE COMPARISON AND VERIFICATION OF STANDARD MEASURES OF LENGTH.

1. The following measures of length can be tested by the Board of Trade Standards Department, Westminster:

Metal measures in the form of 'ribands' or 'tapes':

100 links or 66 feet.
50 links or 33 feet.
100 feet.
50 feet.
25 feet.
20 metres.
10 metres.

2. The whole or total length only of each of the above measures will be tested, except in the case of a standard measure required for survey purposes, when the corrected values of each part or interval of the measure will be given, *e.g.* every 5 metres on 20 metres, or every 10 feet on 100 feet.

3. Unless otherwise required, each measure will be tested under the following condition as to normal tension, 'pull,' or

stretching-weight, when the measure under test is supported throughout its whole length on a plane and even base:

	Metal Measures.
100 link riband - -	10 lb. avoir.
100 feet to 50 feet - -	
20 metres - - -	5 kilograms.
10 metres - - -	

Linked chains, or round-wire chains composed of links and rings and tapes made of linen or other fabric are only verified for certain official purposes.

4. All results are reduced to 62° F. for links and feet and to 0° C. for metres.

The coefficient of linear expansion of a metal measure is taken to be as follows, unless otherwise stated:

	For 1° F.	For 1° C.
Steel - - - - - -	0.00000689	0.00001240
'Invar' or Nickel Steel - (35.7 Nickel, 64.3 Steel.)	0.000000487	0.000000877

5. The following design of stamp or mark of verification (including the year) is placed on a verified measure:

Metal measures should have a brass disc (½-inch diameter) affixed upon which to place the official stamp.

6. In certain cases Treasury fees are required, particulars of which can be obtained at the Standards Office. Fees are not payable on measures for Government Departments or for Local Authorities.

A certificate of verification is given with each measure, in which its error or difference from Standard is stated, and also, in some instances, the modulus of elasticity and 'sag' of a chain.

In standard steel tapes for the use of local Inspectors of Weights and Measures an error in manufacture of 0.1 inch is allowed in excess or deficiency. In other steel standards 0.25 inch is allowed, and in linen tapes 0.5 inch is permitted.

Metric measures should be accurate to about 5 millimetres in 20 metres or to one four-thousandth of the whole length. The verification of measures can be carried out to nearly one four-thousandth part of the whole length.

The above regulations were issued by the Board of Trade Standards Department on the 1st of August, 1904.

SECTION IV. TACHEOMETRY.

The Use of the Tacheometer in Contouring.

For accurate contouring, a sufficient number of stations should be flagged so that any part of the ground is not more than about 1200 feet distant from at least one station, this being about the limit for accurate reading with the usual 5-inch instrument. The levels of the stations should then be determined, and their positions fixed by triangulation in the following manner. When the instrument is levelled up over a station, set it so that the clamped bottom plate has always the same position relative to the true or to the magnetic meridian. This is done by clamping the top plate at the known bearing which the instrument station makes with the back-sight, and then directing the telescope on the back sight with the bottom plate unclamped. The bearing of each sight can thus be booked direct, which saves time in plotting. The angles to all the fixed stations to be located by triangulation should be carefully read and booked before any staff readings are taken. With one man observing and another booking, two or even three staff men can be kept going. Great care should be insisted on in the holding of the staffs perpendicularly, more especially at a point above or below the level of the instrument station, where the sight has to be taken with an inclined telescope. The form of field book given on the following page is recommended.

A pocket steel tape 6 feet long, in a circular metal case and winding up by means of a spring, will be found very convenient for measuring the height of the instrument. In setting up at a

Specimen Page of Field Book.

Field | *Office*

Inst. Stn.	Hght. Inst.	Sighted Stn.	Bearing.	Vert. Angle.	Wires.	Distances. Slope.	Hor.	Vert.	Rise.	Fall.	Axis Level.	Red. Level.	Remarks.
$\triangle B$	4.54										+91.89	+ 87.35	
		1	73° 15′	83° 40′	10.87 9.00 7.13	374	369.45	+41.01	32.01			+123.90	
		2	129° 43′	level	8.95 7.21 5.47		348			7.21		+ 84.68	
		3	4° 18′	94° 21′	10.48 9.00 7.52	296	294.06	−23.92		32.92		+ 58.97	

station, first level up, then take height of instrument (from centre of telescope axis to top of peg), then set bottom plate to correct bearing as already described. Take sights with a level telescope where possible, so as to save calculation in the office. Book the readings of the top, middle and bottom wires in the same column. When sighting to the rise or dip, bring the middle wire on to the same even number on the staff whenever possible, as an error in the reading of the top or bottom wire can then be easily detected when booking, and there is less liability to error in working out reduced levels. For instance, on sighting an ordinary 16 feet level staff, keep cutting the 9 foot mark with the middle wire, then the sum of the top and bottom wire readings should always be $9 \times 2 = 18$, and the 'Rise' or 'Fall' is more easily calculated. In the office first get the slope distance from the wire readings, then work out the horizontal and vertical readings by multiplying by the constants given in the table on pages 141–171. Enter them up, putting a + sign before the vertical distance for a rise, and a – sign for a fall. Then fill in the Axis Level, which is the Reduced Level + the height of the instrument. In case of a rise (see Sighted Station 1 in field book) *subtract* the middle wire reading from the Vertical Distance and book the result in the 'Rise' column. With a level telescope (see Sighted Station 2 in field book) enter the middle wire reading in the 'Fall' column. In case of a fall (see Sighted Station 3 in field book) *add* the middle wire reading to the Vertical Distance and book result in the 'Fall' column. Although in the specimen page everything is worked out to two decimal places, it is usual to work the Horizontal Distance to the nearest foot, which is sufficiently accurate for plotting.

Corrections for Curvature and Refraction.

Distance.	Correction.	Distance.	Correction.	Distance.	Correction.
300	.002	800	.013	1300	.035
400	.003	900	.017	1400	.040
500	.005	1000	.020	1500	.046
600	.007	1100	.025	1600	.052
700	.010	1200	.030	1700	.059

In + or rise angles, add the correction to the amount of rise in 'Rise' column. *In level distances*, book the correction in the 'Rise' column. *In – or dip angles*, deduct correction from amount of fall in 'Fall' column.

The stadia wires of a tacheometer are usually set to a 'measuring angle' twice the tangent of the half of which is 0.01, *i.e.*, the distance between the wires as read on the staff is 0.01 of the actual distance between the staff and the instrument, and consequently the difference between the top and bottom wire readings × 100 = the slope distance. Tacheometer telescopes are now made with an 'anallatic lens,' by which the stadia readings are referred to the centre of the instrument. If a telescope which is not 'anallatic' be used, a correction for 'focal length' has to be applied to all the readings.

The vertical circles of most tacheometers are graduated so that with a level telescope the right hand vernier is at 90° and the left hand vernier at 270°, with 360° at the tangent screw. Therefore a rise angle reads less, and a dip angle more than 90° on the right hand vernier, which is the one usually read. The following table is arranged for instruments of this type, but with an instrument where the actual rise or dip angle is read direct, add 90° when looking up the constants for the angle.

The horizontal distance and the difference in height are calculated from the slope distance and the vertical angle as follows:

Let G = the slope distance, or 'generating number.'

V = the vertical angle, or inclination of G from the horizontal.

D = the horizontal distance.

H = the vertical distance, or difference in height.

Then $D = G \cos^2 V$

and $H = G \sin V \cos V$.*

The following table gives the values of $\cos^2 V$ and $\sin V \cos V$ for each minute of arc from 0° to an inclination of 30° from the horizontal.

Rule: Multiply the slope distance by the constants given in the table for the vertical angle.

* $H = D \tan V$.

SECTION V. TABLE OF CHORDS.

The Accurate Plotting of Angles on Large Scale Plans by means of Chords.

The TABLE OF CHORDS furnishes a means of laying down angles on paper more accurately than by an ordinary protractor. The procedure is as follows: after having drawn and measured the first side (say *ac*) of the figure to be plotted, describe from its end *c* as a centre, an arc *ny* of sufficient length to subtend the angle at that point. The radius *cn* with which the arc is described should be as great as convenience will permit. It must be decimally sub-divided, to be used as a scale for laying down the

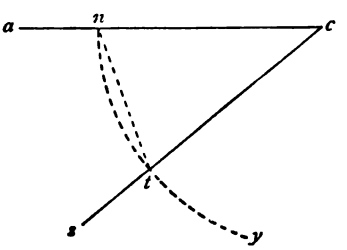

FIG. 3.

chords taken from the table, in which their lengths are given in terms of the radius taken as 1. Having described the arc, find in the table the length of the chord *nt* corresponding to the angle *act*. Suppose this angle to be 45°, the corresponding chord is .7654. Therefore from *n* lay off the chord *nt*, equal to .7654 of the radius-scale; and the line *cs* drawn through the point *t* will form the required angle *act* of 45°. The degree of accuracy attained will evidently depend on the length of the radius, and the care taken in drafting. The dividers in boxes of instruments are rarely fit for accurate arcs of more than about 6 inches diameter. For larger radii the beam-compass is the best instrument to use, or if not obtainable, a straight strip of paper with the length of the radius marked on one edge; by laying it from *c* toward *s*, and at the same time placing another strip (with one edge divided to a radius-scale) from *n* toward *t*, we can by trial find their exact point of intersection at the required point *t*. The fastest method of plotting the chords is by the use of a beam-compass and a $\frac{1}{1000}$ scale, the compass being set to the length of the scale.

Table of Chords, in parts of a radius 1; for protracting.

* From *The Smithsonian Geographical Tables*, Washington, 1906, p. 23.

Table of Squares, Cubes, Square Roots, and Cube Roots of Numbers from 1 to 1000.*

In the roots, wherever the effect of a fifth decimal would be to add 1 to the fourth and final decimal, the addition has been made.

No.	Square.	Cube.	Sq. Rt.	Cu. Rt.	No.	Square.	Cube.	Sq. Rt.	Cu. Rt.
1	1	1	1.	1.	51	2601	132651	7.1414	3.7084
